All download copies of the slides and/or lecture recordings are for personal use only. Students must destroy these copies within 30 days after receipt of final course evaluations.

Addressing Modes

Note that, the ARM assembly language and the RTL language have two different interpretations to the square brackets.

<u>Instruction</u>	<u>RTL form</u>	<u>Description</u>
ADD r0 , r1, #Q	$[r0] \leftarrow [r1] + Q$	Literal: Add the integer Q to the content of register r1 and store the result in r0
LDR r0 , Mem	$[r0] \leftarrow [Mem]$	Direct (i.e., <i>absolute</i>): Load the content of memory-location Mem into register r0. <i>This addressing mode is not supported by ARM but is supported by all CISC processors</i>
LDR r0 , [r1]	$[r0] \leftarrow [[r1]]$	Register Indirect: Load r0 with the content of the memory-location pointed at by r1 <i>The memory-location is given by the contents of a register (that is why we call it Register Indirect)</i>

❑ This is also called:

- *Indexed*
- *Pointer-based*

- ❑ The **ARM** lacks a simple memory *direct* (i.e., *absolute*) addressing mode (i.e., *does not* have an LDR **r0**, address instruction that implements direct addressing to load the contents of a memory-location denoted by address into a register.)

Register Indirect Addressing

- In **ARM**, the register indirect addressing is **indicated** by means of **square brackets**; for example,

```
LDR r1, [r0]           ; [r0] ← [[r1]]  
                        ; Load r1 with the content of  
                        ; the memory-location pointed at by r0
```

FIGURE 3.31

Register indirect addressing

If we look to the memory as an array, then "LDR **r1**, [**r0**]" means $r1 = \text{memory}[r0]$.

© Cengage Learning 2014

Register Indirect Addressing

- ❑ Consider what happens if we next execute

```
ADD r0, r0, #4      ; [r0] ← [r0] + 4
                    ; Add 4 to the contents of register r0
                    ; i.e., increment the pointer by one word
```
- ❑ Figure 3.32 demonstrates the effect of incrementing the pointer register. It now points to the next location in memory.
- ❑ This allows us to use the same instruction (**LDR r1, [r0]**) to access a sequence of memory-locations; for example, a list, matrix, vector, array, or table.

FIGURE 3.32

Effect of incrementing the pointer register

The pointer register points to location $n + 4$ in memory.

After accessing memory via a pointer in register $r0$, adding 4 to the contents of $r0$ means that the pointer now points at the next word in memory.

Register Indirect Addressing with an Offset

- ❑ **ARM** supports a memory-addressing mode where the *effective address* of an operand is **computed by adding** the *contents of a register* to a *literal offset* encoded into the load/store instruction.
The literal offset must be preceded by “#” sign
- ❑ This addressing mode is often called *base plus displacement addressing*.
- ❑ Figure 3.33 illustrates the instruction `LDR r0, [r1, #4]`. The effective address is the sum of the content of the pointer register r1 plus offset 4; that is, the operand is 4 bytes after the address specified by the pointer.
- ❑ In *base plus displacement addressing* mode,
 - *the literal offset is a true 12-bit literal (0–4095), not 0–255 and a rotation as in the literals.*

FIGURE 3.33 Register indirect addressing with an offset

Register Indirect Addressing with an Offset

- ❑ The following fragment of code demonstrates the use of offsets to implement array access.
- ❑ *Note that: constants (defined by EQU here) **cannot** be changed at runtime.*

```
Sun EQU 0           ;offsets for days of the week
Mon EQU 4
Tue EQU 8
Wed EQU 12
Thu EQU 16
Fri EQU 20
Sat EQU 24
```

To store the address of Week
in r0, you may also use
LDR r0,=Week

If “STR r4,[r0]” means memory[r0] = r4,
then
“STR r4,[r0,#4]” means memory[r0+4] = r4

```
ADR r0, Week           ;r0 points to array Week
LDR r2,[r0,#Tue]        ;Load the data for Tuesday into r2
LDR r3,[r0,#Wed]        ;Load the data for Wednesday day into r2
ADD r4,r2,r3            ;Add Tuesday and Wednesday
STR r4,[r0,#Mon]        ;Store the result in Monday
```

```
Week DCD 0x11111111    ;data for day 1 (Sunday)
     DCD 0x22222222    ;data for day 2 (Monday)
     DCD 0x33333333    ;data for day 3 (Tuesday)
     DCD 0x44444444    ;data for day 4 (Wednesday)
     DCD 0x55555555    ;data for day 5 (Thursday)
     DCD 0x66666666    ;data for day 6 (Friday)
     DCD 0x77777777    ;data for day 7 (Saturday)
```

Register Indirect Addressing with an Offset

NOP is a pseudo instruction.

The machine language code for it is "E1A00000".

Decode this machine language code to know the actual instruction to be executed.

The screenshot shows the Keil uVision4 IDE with the following components:

A blue callout bubble contains the text: "NOP means No Operation. It has no use in this context."

Program counter Relative Addressing

- ❑ Any **ARM** register can be used to implement register indirect addressing.
- ❑ If **r15** (i.e., *program counter*) is used as a *pointer register* to access an operand, the resulting address is called *program counter relative addressing*.
 - The operand-location is
 - specified with respect to the current code location.
 - Moving the code and its associated data to a different location in memory will not require any recalculation for operand addresses.

- ❑ Consider the instruction

LDR **r0**, [r15, #100]

- The operand is specified as 100 bytes from the content of **r15**.
- This is *not* 100 bytes from the “LDR **r0**, [r15, #100]” instruction.
- Note that, the **PC** (**r15**) is incremented after fetching an instruction.
 - The **ARM**'s **PC** is actually 8 bytes after the current instruction, i.e., **r0** will be loaded with the value located 108 bytes away from the instruction.
(*This is due to the use of the pipelining mechanism that overlaps operations*)

Register Indirect Addressing with Base and Index Registers

- ❑ You can specify the offset as a second register so that you can use a *dynamic offset* that can be modified at runtime (See Figure 3.35).

LDR **r2**, [r0, r1] ; [r2] ← [[r0] + [r1]] load r2 with
 ; the location pointed at by r0 + r1

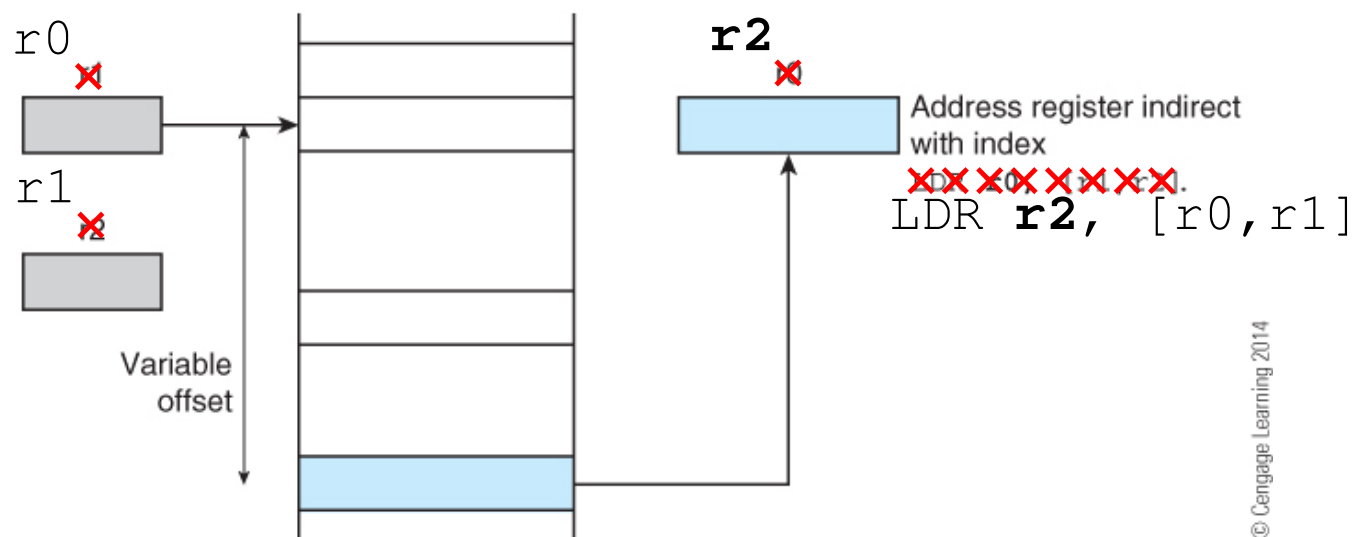

The above instruction and the figure in the book (page 188 - 189) are *not* compatible.

You should change one of them.

If "LDR **r2**, [r0]" means $r2 = \text{memory}[r0]$,
 then
 "LDR **r2**, [r0, r1]" means $r2 = \text{memory}[r0+r1]$

FIGURE 3.35

Indexed addressing with a register offset

Register Indirect Addressing with Base and Index Registers + Scaling

- In this example below, register r1 is multiplied by 4.
 - This allows you to use a scaled offset when dealing with arrays.

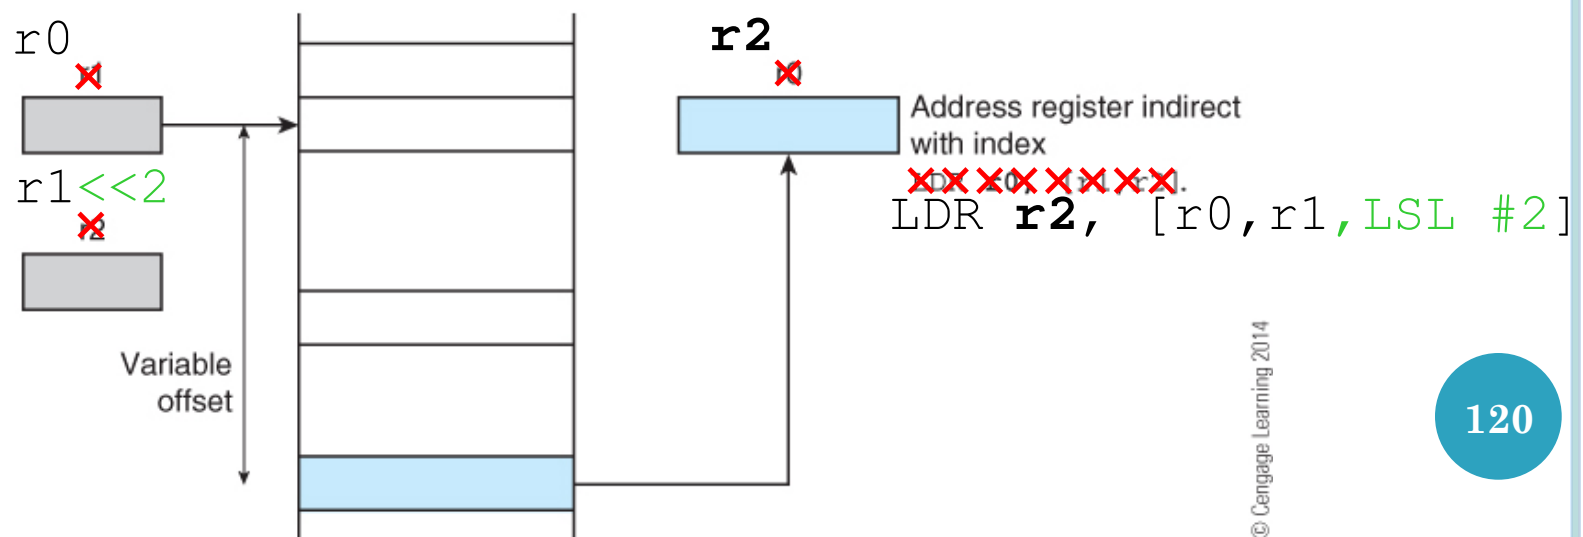

LDR **r2**, [r0, r1, LSL #2] ; [r2] ← [[r0] + [r1] × 4] Scale r1 by 4

If “LDR **r2**, [r0]” means $r2 = \text{memory}[r0]$,
then

“LDR **r2**, [r0, r1, LSL #2]” means $r2 = \text{memory}[r0 + r1 \times 4]$

FIGURE 3.35

Indexed addressing with a register offset

Register Indirect Addressing with Base and Index Registers + Scaling

- ❑ **Example:** Consider the following fragment of C code, where *j* is a long int array:

```
for(i = 0; i < 21; i++)
{
    j[i] = j[i] + 10;
}
```

Array *j* has 21 elements (indexed from 0 to 20 and we want to add 10 to each element of this array.

- ❑ This C code can be translated into **ARM** assembly language as follow

MOV	r0 , #0		;Use r0 as the counter i
ADR	r8 , j		;Initialize counter i to zero
			;Base register r8 points to
			;array j (pseudo instruction)
Loop LDR	r1 , [r8, r0 , lsl #2]		;REPEAT Get j[i]
ADD	r1 , r1, #10		; Add 10 to j[i]
STR	r1, [r8, r0 , lsl #2]		; Save j[i]
ADD	r0 , r0, #1		; Increment loop counter i
CMP	r0, #21		; Compare loop counter with
			; terminal value + 1
BNE	Loop		;UNTIL i = 21

page 186

Not correct
in the book
page 186

Auto-indexing Addressing Mode

- ❑ Elements in an array, or similar data structure, are frequently accessed sequentially.
 - To facilitate such action, *Auto-indexing addressing* modes have been implemented.
 - In *Auto-indexing addressing* modes, the *pointer is automatically adjusted* to point at the next element *before* or *after* it is used, i.e., similar to **memory[++r1]** and **memory [r1++]**, respectively, in C and similar to **memory[--r1]** and **memory [r1--]**, respectively, in C
- ❑ **ARM**'s auto-indexing modes are implemented by
 - adding an offset to the base register
- ❑ **ARM** implements two auto-indexing modes
 - Auto-indexing *pre*-indexed
 - Auto-indexing *post*-indexed

In ARM, The amount of the increment or decrement can be any value, not just an increment or decrement by 1, depending on the problem in hand.

Auto-indexing Pre-indexed Addressing Mode

- ❑ *Auto-indexing pre-indexed* addressing
 - increments the base register by an offset
 - accesses the operand at the location pointed to by the *updated* base register.
 - similar to `memory[++r1]` in C
- ❑ ARM's *auto-indexing pre-indexed* addressing mode is
 - *indicated by* appending the suffix **!** to the end of the address.

- ❑ Consider the following ARM instruction:

```
LDR    r0, [r1, #8]!    ;load r0 with the word pointed at by
                        ;register r1 plus 8 and update the
                        ;pointer by adding 8 to r1
```

The amount of the increment can be any value, depending on the problem in hand.

- ❑ The RTL definition of this instruction is given by

$$[r0] \leftarrow [[r1] + 8] \quad \text{Access the memory 8 bytes beyond the base register } r1$$

$$[r1] \leftarrow [r1] + 8 \quad \text{Update the pointer (base register) by adding the offset}$$
- ❑ This *auto-indexing pre-indexed mode* does not cost additional execution time, because it is performed in parallel with memory access.

Auto-indexing Pre-indexed Addressing Mode

- Consider this example of adding two arrays (each array is 8 elements of 4 bytes each).

Len	EQU	8		;let's make the arrays 8 words long
ADR	r0 ,	A	- 4	;register r0 points at 4 bytes prior
				;to the beginning of array A
ADR	r1 ,	B	- 4	;register r1 points at 4 bytes prior
				;to the beginning of array B
ADR	r2 ,	C	- 4	;register r2 points at 4 bytes prior
				;to the beginning of array C
MOV	r5 ,	#Len		;use register r5 as a loop counter
Loop	LDR	r3 ,	[r0,#4]!	;get element of A
	LDR	r4 ,	[r1,#4]!	;get element of B
	ADD	r3 ,	r3, r4	;add two elements
	STR	r3 ,	[r2,#4]!	;store the sum in C
	SUBS	r5 ,	r5, #1	;test for end of loop
	BNE	Loop		;repeat until all done

Annotations:

- 0x6... means 0110... (NZCV...)**
- Why C = 1?**

Auto-indexing Post-indexed Addressing Mode

- ❑ Auto-indexing *post-indexed* addressing
 - first accesses the operand at the location pointed to by the base register,
 - *then* increments the base register.
 - similar to `memory[r1++]` in in C
- ❑ ARM's *auto-indexing post-indexed* is *denoted by placing the offset outside the square*.

The amount of the increment can be any value, depending on the problem in hand.

- ❑ Example:

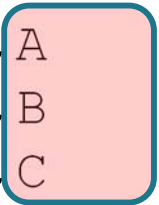

```
LDR    r0, [r1], #8 ; load r0 with the word pointed at by r1
                     ; now do the post-indexing by adding 8 to r1
```

- ❑ The RTL definition of this instruction is:

$[r0] \leftarrow [[r1]]$	Access the memory address in base register r1
$[r1] \leftarrow [r1] + 8$	Update pointer (base register) by adding offset

Auto-indexing Post-indexed Addressing Mode

- ❑ Consider this example of the addition of two arrays (8 elements each, 4 bytes each).

Len	EQU	8		;let's make the arrays 8 words long
ADR	r0 ,	A		;register r0 points at array A
ADR	r1 ,	B		;register r1 points at array B
ADR	r2 ,	C		;register r2 points at array C
MOV	r5 ,	#Len		;use register r5 as a loop counter
Loop	LDR	r3 , [r0], #4		;get element of A
	LDR	r4 , [r1], #4		;get element of B
	ADD	r3 , r3, r4		;add two elements
	STR	r3 , [r2], #4		;store the sum in C
	SUBS	r5 , r5, #1		;test for end of loop
	BNE	Loop		;repeat until all done

Register Indirect Addressing with Offset

- (a) `LDR r0, [r1, #12]`
 Offset added to base register to generate effective address. Operand accessed at effective address. **Base register remains unchanged.**

Why do not we have "Use the original base pointer then adjust pointer" with "Do NOT write-back (do not update) the adjusted pointer"?

- (b) `LDR r0, [r1, #12]!`
 Offset added to base register to generate effective address. Operand accessed at effective address. **Base register updated after access.**

- (c) `LDR r0, [r1], #12`
 Effective address specified by base register. Operand accessed at effective address. **Offset added to base register after the access.**

Summary of ARM Addressing Modes

(b) `LDR r0, [r1, #12]!`
Offset added to base register to generate effective address. Operand accessed at effective address. Base register updated after access.

(c) `LDR r0, [r1], #12`
Effective address specified by base register. Operand accessed at effective address. Offset added to base register after the access.

The offset in these two cases can also be an index register, for example, "r2" instead of "#12", or can be an index register with shift, for example, "r2, LSL#3" instead of "#12".
