

# **Pushdown Automata**

Chapter 12

# Recognizing Context-Free Languages

We need a device similar to an FSM except that it needs more power.

The insight: Precisely what it needs is a stack, which gives it an unlimited amount of memory with a restricted structure.

Example: Bal (the balanced parentheses language)

$(((( )))$

# Definition of a Pushdown Automaton

$M = (K, \Sigma, \Gamma, \Delta, s, A)$ , where:

$K$  is a finite set of **states**

$\Sigma$  is the **input alphabet**

$\Gamma$  is the **stack alphabet**

$s \in K$  is the **initial state**

$A \subseteq K$  is the set of **accepting states**, and

$\Delta$  is the **transition relation**. It is a finite subset of

$$\underbrace{(K \times (\Sigma \cup \{\varepsilon\}) \times \Gamma^*)}_{\text{state} \quad \text{input or } \varepsilon \quad \text{string to pop from top of stack}} \times \underbrace{(K \times \Gamma^*)}_{\text{state} \quad \text{string of to push on top of stack}}$$

state

input or  $\varepsilon$

string  
to pop  
from top  
of stack

state

string of  
to push  
on top  
of stack

# Definition of a Pushdown Automaton

A **configuration** of  $M$  is an element of  $K \times \Sigma^* \times \Gamma^*$ .

The **initial configuration** of  $M$  is  $(s, w, \varepsilon)$ .

# Yields

Let  $c \in \Sigma \cup \{\varepsilon\}$ ,  $\gamma_1, \gamma_2, \gamma \in \Gamma^*$ , and  $w \in \Sigma^*$ .

Then:

$(q_1, cw, \gamma_1\gamma) \vdash_M (q_2, w, \gamma_2\gamma)$  iff  $((q_1, c, \gamma_1), (q_2, \gamma_2)) \in \Delta$ .

Let  $\vdash_M^*$  be the reflexive, transitive closure of  $\vdash_M$ .

$C_1$  **yields** configuration  $C_2$  iff  $C_1 \vdash_M^* C_2$

# Computations

A **computation** by  $M$  is a finite sequence of configurations  $C_0, C_1, \dots, C_n$  for some  $n \geq 0$  such that:

- $C_0$  is an initial configuration,
- $C_n$  is of the form  $(q, \varepsilon, \gamma)$ , for some state  $q \in K_M$  and some string  $\gamma$  in  $\Gamma^*$ , and
- $C_0 \vdash_M C_1 \vdash_M C_2 \vdash_M \dots \vdash_M C_n$ .

# Nondeterminism

If  $M$  is in some configuration  $(q_1, s, \gamma)$  it is possible that:

- $\Delta$  contains exactly one transition that matches.
- $\Delta$  contains more than one transition that matches.
- $\Delta$  contains no transition that matches.

# Accepting

A computation  $C$  of  $M$  is an **accepting computation** iff:

- $C = (s, w, \varepsilon) \vdash_M^* (q, \varepsilon, \varepsilon)$ , and (empty stack)
- $q \in A$ . (accepting state)

$M$  **accepts** a string  $w$  iff at least one of its computations accepts.

Other paths may:

- Read all the input and halt in a nonaccepting state,
- Read all the input and halt in an accepting state with the stack not empty,
- Loop forever and never finish reading the input, or
- Reach a dead end where no more input can be read.

The **language accepted by**  $M$ , denoted  $L(M)$ , is the set of all strings accepted by  $M$ .

# Rejecting

A computation  $C$  of  $M$  is a **rejecting computation** iff:

- $C = (s, w, \varepsilon) \vdash_M^* (q, w', \alpha)$ ,
- $C$  is not an accepting computation, and
- $M$  has no moves that it can make from  $(q, w', \alpha)$ .

$M$  **rejects** a string  $w$  iff all of its computations reject.

So note that it is possible that, on input  $w$ ,  $M$  neither accepts nor rejects.

# A PDA for Balanced Parentheses

$M = (K, \Sigma, \Gamma, \Delta, s, A)$ , where:

$K = \{s\}$  the states  
 $\Sigma = \{ (, ) \}$  the input alphabet  
 $\Gamma = \{ ( \}$  the stack alphabet  
 $A = \{s\}$

$\Delta$  contains:

$((s, (, \epsilon^{\dagger}), (s, ( ))$   
 $((s, ), ( ), (s, \epsilon))$

$\dagger$  This does not mean that the stack is empty

**A PDA for  $A_n B_n = \{a^n b^n : n \geq 0\}$**

# A PDA for $\{wcw^R: w \in \{a, b\}^*\}$

$M = (K, \Sigma, \Gamma, \Delta, s, A)$ , where:

$K = \{s, f\}$  the states  
 $\Sigma = \{a, b, c\}$  the input alphabet  
 $\Gamma = \{a, b\}$  the stack alphabet  
 $A = \{f\}$  the accepting states

$\Delta$  contains:  $((s, a, \varepsilon), (s, a))$   
 $((s, b, \varepsilon), (s, b))$   
 $((s, c, \varepsilon), (f, \varepsilon))$   
 $((f, a, a), (f, \varepsilon))$   
 $((f, b, b), (f, \varepsilon))$

# A PDA for $\{a^n b^{2n} : n \geq 0\}$

# A PDA for PalEven = { $ww^R$ : $w \in \{a, b\}^*$ }

$$S \rightarrow \varepsilon$$

$$S \rightarrow aSa$$

$$S \rightarrow bSb$$

A PDA:

**A PDA for  $\{w \in \{a, b\}^* : \#_a(w) = \#_b(w)\}$**

# Accepting Mismatches

$$L = \{a^m b^n : m \neq n; m, n > 0\}$$

Start with the case where  $n = m$ :

- If stack and input are empty, halt and reject.
- If input is empty but stack is not ( $m > n$ ) (accept):
- If stack is empty but input is not ( $m < n$ ) (accept):

# Accepting Mismatches

$$L = \{a^m b^n : m \neq n; m, n > 0\}$$

- If input is empty but stack is not ( $m > n$ ) (accept):

# Accepting Mismatches

$$L = \{a^m b^n : m \neq n; m, n > 0\}$$

- If stack is empty but input is not ( $m < n$ ) (accept):

# Putting It Together

$$L = \{a^m b^n : m \neq n; m, n > 0\}$$

- Jumping to the input clearing state 4:  
Need to detect bottom of stack.
- Jumping to the stack clearing state 3:  
Need to detect end of input.

$$A^n B^n C^n \quad \text{vs} \quad \neg A^n B^n C^n$$

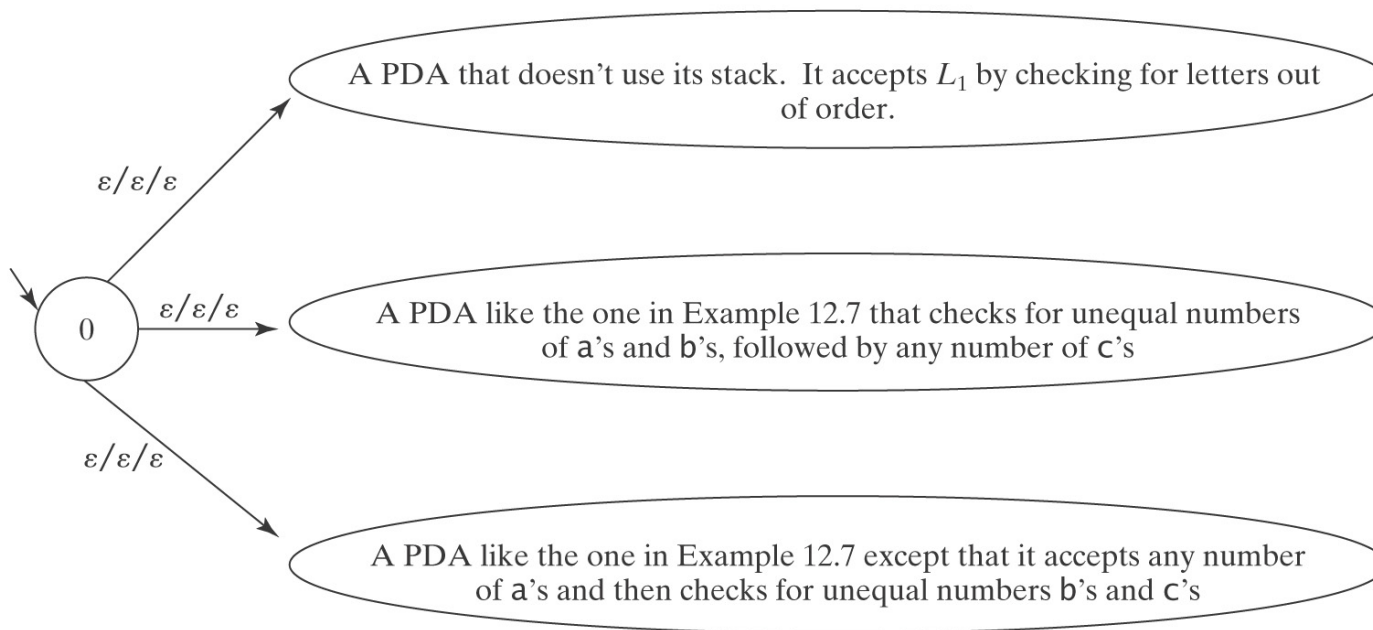

Consider  $A^n B^n C^n = \{a^n b^n c^n : n \geq 0\}$ .

PDA for  $A^n B^n C^n$ ?

Now consider  $L = \neg A^n B^n C^n$ .  $L$  is the union of two languages:

1.  $\{w \in \{a, b, c\}^* : \text{the letters are out of order}\}$ , and
2.  $\{a^i b^j c^k : i, j, k \geq 0 \text{ and } (i \neq j \text{ or } j \neq k)\}$  (in other words, unequal numbers of a's, b's, and c's).

# A PDA for $L = \neg A^n B^n C^n$

# Are the Context-Free Languages Closed Under Complement?

$\neg A^n B^n C^n$  is context free.

If the CF languages were closed under complement, then

$$\neg \neg A^n B^n C^n = A^n B^n C^n$$

would also be context-free.

But we will prove that it is not.

$$L = \{a^n b^m c^p : n, m, p \geq 0 \text{ and } n \neq m \text{ or } m \neq p\}$$

$S \rightarrow NC$  /\*  $n \neq m$ , then arbitrary c's

$S \rightarrow QP$  /\* arbitrary a's, then  $p \neq m$

$N \rightarrow A$  /\* more a's than b's

$N \rightarrow B$  /\* more b's than a's

$A \rightarrow a$

$A \rightarrow aA$

$A \rightarrow aAb$

$B \rightarrow b$

$B \rightarrow Bb$

$B \rightarrow aBb$

$C \rightarrow \varepsilon \mid cC$  /\* add any number of c's

$P \rightarrow B'$  /\* more b's than c's

$P \rightarrow C'$  /\* more c's than b's

$B' \rightarrow b$

$B' \rightarrow bB'$

$B' \rightarrow bB'c$

$C' \rightarrow c \mid C'c$

$C' \rightarrow C'c$

$C' \rightarrow bC'c$

$Q \rightarrow \varepsilon \mid aQ$  /\* prefix with any number of a's

# PDAs and Context-Free Grammars

**Theorem 12.3:** The class of languages accepted by PDAs is exactly the class of context-free languages.

Recall: context-free languages are languages that can be defined with context-free grammars.

**Restate theorem:**

Can describe with context-free grammar

=

Can accept by PDA

# Going One Way

**Theorem 12.1:** Each context-free language is accepted by some PDA.

**Proof** (by construction) (not required for midterm !!)

The idea: Let the stack do the work.

Two approaches:

- Top down
- Bottom up

# Top Down

The idea: Let the stack keep track of expectations.

## Example: Arithmetic expressions

$$E \rightarrow E + T$$

$$E \rightarrow T$$

$$T \rightarrow T * F$$

$$T \rightarrow F$$

$$F \rightarrow (E)$$

$$F \rightarrow id$$

$$(1) (q, \varepsilon, E), (q, E+T)$$

$$(2) (q, \varepsilon, E), (q, T)$$

$$(3) (q, \varepsilon, T), (q, T*F)$$

$$(4) (q, \varepsilon, T), (q, F)$$

$$(5) (q, \varepsilon, F), (q, (E) )$$

$$(6) (q, \varepsilon, F), (q, id)$$

$$(7) (q, id, id), (q, \varepsilon)$$

$$(8) (q, (, ( ), (q, \varepsilon)$$

$$(9) (q, ), ) ), (q, \varepsilon)$$

$$(10) (q, +, +), (q, \varepsilon)$$

$$(11) (q, *, *), (q, \varepsilon)$$

# A Top-Down Parser

The construction in general:

$M = (\{p, q\}, \Sigma, V, \Delta, p, \{q\})$ , where  $\Delta$  contains:

- The start-up transition  $((p, \epsilon, \epsilon), (q, S))$ .
- For each rule  $X \rightarrow s_1 s_2 \dots s_n$  in  $R$ , the transition:  
 $((q, \epsilon, X), (q, s_1 s_2 \dots s_n))$ .
- For each character  $c \in \Sigma$ , the transition:  
 $((q, c, c), (q, \epsilon))$ .

# Example: $L = \{a^n b^* a^n\}$

$(p, \varepsilon, \varepsilon), (q, S)$   
 $(q, a, a), (q, \varepsilon)$   
 $(q, b, b), (q, \varepsilon)$

$(q, \varepsilon, S), (q, \varepsilon)$   
 $(q, \varepsilon, S), (q, B)$   
 $(q, \varepsilon, S), (q, aSa)$   
 $(q, \varepsilon, B), (q, \varepsilon)$   
 $(q, \varepsilon, B), (q, bB)$

CF grammar:

$S \rightarrow \varepsilon$   
 $S \rightarrow B$   
 $S \rightarrow aSa$   
 $B \rightarrow \varepsilon$   
 $B \rightarrow bB$

input = a a b b a a

<i>Trans</i>	<i>state</i>	<i>unread input</i>				<i>stack</i>
		p	a	a	b b a a	$\varepsilon$
0	q		a	a	b b a a	S
3	q		a	a	b b a a	aSa
6	q			a	b b a a	Sa
3	q			a	b b a a	aSaa
6	q				b b a a	Saa
2	q				b b a a	Baa
5	q				b b a a	bBaa
7	q				b a a	Baa
5	q				b a a	bBaa
7	q				a a	Baa
4	q				a a	aa
6	q				a	a
6	q				$\varepsilon$	$\varepsilon$

# Going The Other Way

**Theorem 12.2:** If a language is accepted by a pushdown automaton  $M$ , it is context-free (i.e., it can be described by a context-free grammar).

The proof is by construction - very complicated, not required !!

# Nondeterminism, minimality

A PDA  $M$  is **deterministic** iff:

- $\Delta_M$  contains no pairs of transitions that compete with each other
- Whenever  $M$  is in an accepting configuration it has no available moves.

1. **Determinism is strictly less powerful:** There are context-free languages for which no deterministic PDA exists.
2. It is possible that a PDA may
  - not halt,
  - not ever finish reading its input.
3. There exists **no algorithm to minimize** a PDA. It is **undecidable whether a PDA is minimal**.
