

Chapter 2

C Fundamentals

Program: Printing a Pun

```
#include <stdio.h>

int main(void)
{
    printf("To C, or not to C: that is the question.\n");
    return 0;
}
```

- This program might be stored in a file named `pun.c`.
- The file name doesn't matter, but the `.c` extension is often required.

Compiling and Linking

- Before a program can be executed, three steps are usually necessary:
 - **Preprocessing.** The *preprocessor* obeys commands that begin with # (known as *directives*)
 - **Compiling.** A *compiler* translates then translates the program into machine instructions (*object code*).
 - **Linking.** A *linker* combines the object code produced by the compiler with any additional code needed to yield a complete executable program.
- The preprocessor is usually integrated with the compiler.

Compiling and Linking Using `cc`

- To compile and link the `pun.c` program under UNIX, enter the following command in a terminal or command-line window:

```
% cc pun.c
```

The `%` character is the UNIX prompt.

- Linking is automatic when using `cc`; no separate link command is necessary.

Compiling and Linking Using `cc`

- After compiling and linking the program, `cc` leaves the executable program in a file named `a.out` by default.
- The `-o` option lets us choose the name of the file containing the executable program.
- The following command causes the executable version of `pun.c` to be named `pun`:

```
% cc -o pun pun.c
```

The GCC Compiler

- GCC is one of the most popular C compilers.
- GCC is supplied with Linux but is available for many other platforms as well.
- Using this compiler is similar to using `cc`:

```
% gcc -o pun pun.c
```

Integrated Development Environments

- An *integrated development environment (IDE)* is a software package that makes it possible to edit, compile, link, execute, and debug a program without leaving the environment.

The General Form of a Simple Program

- Simple C programs have the form

directives

```
int main(void)
{
    statements
}
```

The General Form of a Simple Program

- C uses { and } in much the same way that some other languages use words like `begin` and `end`.
- Even the simplest C programs rely on three key language features:
 - Directives
 - Functions
 - Statements

Directives

- Before a C program is compiled, it is first edited by a preprocessor.
- Commands intended for the preprocessor are called directives.
- Example:
`#include <stdio.h>`
- `<stdio.h>` is a ***header*** containing information about C's standard I/O library.

Directives

- Directives always begin with a # character.
- By default, directives are one line long; there's no semicolon or other special marker at the end.

Functions

- A *function* is a series of statements that have been grouped together and given a name.
- *Library functions* are provided as part of the C implementation.
- A function that computes a value uses a `return` statement to specify what value it “returns”:
`return x + 1;`

The `main` Function

- The `main` function is mandatory.
- `main` is special: it gets called automatically when the program is executed.
- `main` returns a status code; the value 0 indicates normal program termination.
- If there's no `return` statement at the end of the `main` function, many compilers will produce a warning message.

Statements

- A *statement* is a command to be executed when the program runs.
- `pun.c` uses only two kinds of statements. One is the `return` statement; the other is the *function call*.
- Asking a function to perform its assigned task is known as *calling* the function.
- `pun.c` calls `printf` to display a string:

```
printf("To C, or not to C: that is the question.\n");
```

Statements

- C requires that each statement end with a semicolon.
 - There's one exception: the compound statement.
- Directives are normally one line long, and they don't end with a semicolon.

Printing Strings

- When the `printf` function displays a *string literal*—characters enclosed in double quotation marks—it doesn't show the quotation marks.
- `printf` doesn't automatically advance to the next output line when it finishes printing.
- To make `printf` advance one line, include `\n` (the *new-line character*) in the string to be printed.

Printing Strings

- The statement

```
printf("To C, or not to C: that is the question.\n");
```

could be replaced by two calls of `printf`:

```
printf("To C, or not to C: ");  
printf("that is the question.\n");
```

- The new-line character can appear more than once in a string literal:

```
printf("Brevity is the soul of wit.\n  --Shakespeare\n");
```

Comments

- A *comment* begins with `/*` and end with `*/`.

```
/* This is a comment */
```

- Comments may appear almost anywhere in a program, either on separate lines or on the same lines as other program text.
- Comments may extend over more than one line.

```
/* Name: pun.c  
   Purpose: Prints a bad pun.  
   Author: K. N. King */
```

Comments

- *Warning:* Forgetting to terminate a comment may cause the compiler to ignore part of your program:

```
printf("My ");      /* forgot to close this comment...  
printf("cat ");  
printf("has ");     /* so it ends here */  
printf("fleas");
```

Comments in C99

- In C99, comments can also be written in the following way:

```
// This is a comment
```

- This style of comment ends automatically at the end of a line.
- Advantages of `//` comments:
 - Safer: there's no chance that an unterminated comment will accidentally consume part of a program.
 - Multiline comments stand out better.

Variables and Assignment

- Most programs need to a way to store data temporarily during program execution.
- These storage locations are called *variables*.

Types

- Every variable must have a *type*.
- C has a wide variety of types, including `int` and `float`.
- A variable of type `int` (short for *integer*) can store a whole number such as 0, 1, 392, or -2553 .
 - The largest `int` value is typically 2,147,483,647 but can be as small as 32,767.

Types

- A variable of type `float` (short for *floating-point*) can store much larger numbers than an `int` variable.
- Also, a `float` variable can store numbers with digits after the decimal point, like 379.125.
- Drawbacks of `float` variables:
 - Slower arithmetic
 - Approximate nature of `float` values

Declarations

- Variables must be *declared* before they are used.
- Variables can be declared one at a time:

```
int height;  
float profit;
```

- Alternatively, several can be declared at the same time:

```
int height, length, width, volume;  
float profit, loss;
```

Declarations

- When `main` contains declarations, these must precede statements:

```
int main(void)
{
    declarations
    statements
}
```

- In C99, declarations don't have to come before statements.

Assignment

- A variable can be given a value by means of *assignment*:

```
height = 8;
```

The number 8 is said to be a *constant*.

- Before a variable can be assigned a value—or used in any other way—it must first be declared.

Assignment

- A constant assigned to a `float` variable usually contains a decimal point:

```
profit = 2150.48;
```

- It's best to append the letter `f` to a floating-point constant if it is assigned to a `float` variable:

```
profit = 2150.48f;
```

Failing to include the `f` may cause a warning from the compiler.

Assignment

- An `int` variable is normally assigned a value of type `int`, and a `float` variable is normally assigned a value of type `float`.
- Mixing types (such as assigning an `int` value to a `float` variable or assigning a `float` value to an `int` variable) is possible but not always safe.

Assignment

- Once a variable has been assigned a value, it can be used to help compute the value of another variable:

```
height = 8;  
length = 12;  
width = 10;  
volume = height * length * width;  
/* volume is now 960 */
```

- The right side of an assignment can be a formula (or *expression*, in C terminology) involving constants, variables, and operators.

Printing the Value of a Variable

- `printf` can be used to display the current value of a variable.

- To write the message

Height: *h*

where *h* is the current value of the `height` variable, we'd use the following call of `printf`:

```
printf("Height: %d\n", height);
```

- `%d` is a placeholder indicating where the value of `height` is to be filled in.

Printing the Value of a Variable

- `%d` works only for `int` variables; to print a `float` variable, use `%f` instead.
- By default, `%f` displays a number with six digits after the decimal point.
- To force `%f` to display *p* digits after the decimal point, put `.p` between `%` and `f`.

- To print the line

`Profit: $2150.48`

use the following call of `printf`:

```
printf("Profit: $%.2f\n", profit);
```

Printing the Value of a Variable

- There's no limit to the number of variables that can be printed by a single call of `printf`:

```
printf("Height: %d   Length: %d\n", height, length);
```

Program: Computing the Dimensional Weight of a Box

- Shipping companies often charge extra for boxes that are large but very light, basing the fee on volume instead of weight.
- The usual method to compute the “dimensional weight” is to divide the volume by 166 (the allowable number of cubic inches per pound).
- The `dweight.c` program computes the dimensional weight of a particular box:

Dimensions: 12x10x8

Volume (cubic inches): 960

Dimensional weight (pounds): 6

Program: Computing the Dimensional Weight of a Box

- Division is represented by `/` in C, so the obvious way to compute the dimensional weight would be
`weight = volume / 166;`
- In C, however, when one integer is divided by another, the answer is “truncated”: all digits after the decimal point are lost.
 - The volume of a 12” \times 10” \times 8” box will be 960 cubic inches.
 - Dividing by 166 gives 5 instead of 5.783.

Program: Computing the Dimensional Weight of a Box

- One solution is to add 165 to the volume before dividing by 166:

```
weight = (volume + 165) / 166;
```

- A volume of 166 would give a weight of 331/166, or 1, while a volume of 167 would yield 332/166, or 2.

dweight.c

```
/* Computes the dimensional weight of a 12" x 10" x 8" box */  
  
#include <stdio.h>  
  
int main(void)  
{  
    int height, length, width, volume, weight;  
  
    height = 8;  
    length = 12;  
    width = 10;  
    volume = height * length * width;  
    weight = (volume + 165) / 166;  
  
    printf("Dimensions: %dx%dx%d\n", length, width, height);  
    printf("Volume (cubic inches): %d\n", volume);  
    printf("Dimensional weight (pounds): %d\n", weight);  
  
    return 0;  
}
```

Initialization

- Some variables are automatically set to zero when a program begins to execute, but most are not.
- A variable that doesn't have a default value and hasn't yet been assigned a value by the program is said to be *uninitialized*.
- Attempting to access the value of an uninitialized variable may yield an unpredictable result.
- With some compilers, worse behavior—even a program crash—may occur.

Initialization

- The initial value of a variable may be included in its declaration:

```
int height = 8;
```

The value 8 is said to be an *initializer*.

- Any number of variables can be initialized in the same declaration:

```
int height = 8, length = 12, width = 10;
```

- Each variable requires its own initializer.

```
int height, length, width = 10;  
/* initializes only width */
```

Printing Expressions

- `printf` can display the value of any numeric expression.
- The statements

```
volume = height * length * width;  
printf("%d\n", volume);
```

could be replaced by

```
printf("%d\n", height * length * width);
```

Reading Input

- `scanf` is the C library's counterpart to `printf`.
- `scanf` requires a *format string* to specify the appearance of the input data.
- Example of using `scanf` to read an `int` value:

```
scanf("%d", &i);  
/* reads an integer; stores into i */
```
- The `&` symbol is usually (but not always) required when using `scanf`.

Reading Input

- Reading a `float` value requires a slightly different call of `scanf`:

```
scanf ("%f", &x) ;
```

- `"%f"` tells `scanf` to look for an input value in `float` format (the number may contain a decimal point, but doesn't have to).

Program: Computing the Dimensional Weight of a Box (Revisited)

- `dweight2.c` is an improved version of the dimensional weight program in which the user enters the dimensions.
- Each call of `scanf` is immediately preceded by a call of `printf` that displays a *prompt*.

dweight2.c

```
/* Computes the dimensional weight of a box from input provided by the user */

#include <stdio.h>

int main(void)
{
    int height, length, width, volume, weight;

    printf("Enter height of box: ");
    scanf("%d", &height);
    printf("Enter length of box: ");
    scanf("%d", &length);
    printf("Enter width of box: ");
    scanf("%d", &width);
    volume = height * length * width;
    weight = (volume + 165) / 166;

    printf("Volume (cubic inches): %d\n", volume);
    printf("Dimensional weight (pounds): %d\n", weight);

    return 0;
}
```

Program: Computing the Dimensional Weight of a Box (Revisited)

- Sample output of program:

```
Enter height of box: 8
```

```
Enter length of box: 12
```

```
Enter width of box: 10
```

```
Volume (cubic inches): 960
```

```
Dimensional weight (pounds): 6
```

- Note that a prompt shouldn't end with a new-line character.

Defining Names for Constants

- `dweight.c` and `dweight2.c` rely on the constant 166, whose meaning may not be clear to someone reading the program.
- Using a feature known as *macro definition*, we can name this constant:

```
#define INCHES_PER_POUND 166
```

Defining Names for Constants

- When a program is compiled, the preprocessor replaces each macro by the value that it represents.
- During preprocessing, the statement

```
weight = (volume + INCHES_PER_POUND - 1) / INCHES_PER_POUND;
```

will become

```
weight = (volume + 166 - 1) / 166;
```

Defining Names for Constants

- The value of a macro can be an expression:

```
#define RECIPROCAL_OF_PI (1.0f / 3.14159f)
```
- If it contains operators, the expression should be enclosed in parentheses.
- Using only upper-case letters in macro names is a common convention.

Program: Converting from Fahrenheit to Celsius

- The `celsius.c` program prompts the user to enter a Fahrenheit temperature; it then prints the equivalent Celsius temperature.
- Sample program output:
Enter Fahrenheit temperature: 212
Celsius equivalent: 100.0
- The program will allow temperatures that aren't integers.

celsius.c

```
/* Converts a Fahrenheit temperature to Celsius */  
  
#include <stdio.h>  
  
#define FREEZING_PT 32.0f  
#define SCALE_FACTOR (5.0f / 9.0f)  
  
int main(void)  
{  
    float fahrenheit, celsius;  
  
    printf("Enter Fahrenheit temperature: ");  
    scanf("%f", &fahrenheit);  
  
    celsius = (fahrenheit - FREEZING_PT) * SCALE_FACTOR;  
  
    printf("Celsius equivalent: %.1f\n", celsius);  
  
    return 0;  
}
```

Program: Converting from Fahrenheit to Celsius

- Defining `SCALE_FACTOR` to be `(5.0f / 9.0f)` instead of `(5 / 9)` is important.
- Note the use of `% .1f` to display `celsius` with just one digit after the decimal point.

Identifiers

- Names for variables, functions, macros, and other entities are called *identifiers*.
- An identifier may contain letters, digits, and underscores, but must begin with a letter or underscore:

```
times10    get_next_char    _done
```

It's usually best to avoid identifiers that begin with an underscore.

- Examples of illegal identifiers:

```
10times    get-next-char
```

Identifiers

- C is *case-sensitive*: it distinguishes between upper-case and lower-case letters in identifiers.
- For example, the following identifiers are all different:

j ob j oB j Ob j OB Job JoB JOB JOB

Identifiers

- Many programmers use only lower-case letters in identifiers (other than macros), with underscores inserted for legibility:

`symbol_table current_page name_and_address`

- Other programmers use an upper-case letter to begin each word within an identifier:

`symbolTable currentPage nameAndAddress`

- C places no limit on the maximum length of an identifier.

Keywords

- The following *keywords* can't be used as identifiers:

| | | | |
|----------|----------|-----------|-------------|
| auto | enum | restrict* | unsigned |
| break | extern | return | void |
| case | float | short | volatile |
| char | for | signed | while |
| const | goto | sizeof | _Bool* |
| continue | if | static | _Complex* |
| default | inline* | struct | _Imaginary* |
| do | int | switch | |
| double | long | typedef | |
| else | register | union | |

*C99 only

Keywords

- Keywords (with the exception of `_Bool`, `_Complex`, and `_Imaginary`) must be written using only lower-case letters.
- Names of library functions (e.g., `printf`) are also lower-case.

Layout of a C Program

- A C program is a series of *tokens*.
- Tokens include:
 - Identifiers
 - Keywords
 - Operators
 - Punctuation
 - Constants
 - String literals

Layout of a C Program

- The statement

```
printf("Height: %d\n", height);
```

consists of seven tokens:

| | |
|-----------------------------|----------------|
| <code>printf</code> | Identifier |
| <code>(</code> | Punctuation |
| <code>"Height: %d\n"</code> | String literal |
| <code>,</code> | Punctuation |
| <code>height</code> | Identifier |
| <code>)</code> | Punctuation |
| <code>;</code> | Punctuation |

Layout of a C Program

- The amount of space between tokens usually isn't critical.
- At one extreme, tokens can be crammed together with no space between them, except where this would cause two tokens to merge:

```
/* Converts a Fahrenheit temperature to Celsius */  
#include <stdio.h>  
#define FREEZING_PT 32.0f  
#define SCALE_FACTOR (5.0f/9.0f)  
int main(void){float fahrenheit,celsius;printf(  
"Enter Fahrenheit temperature: ");scanf("%f", &fahrenheit);  
celsius=(fahrenheit-FREEZING_PT)*SCALE_FACTOR;  
printf("Celsius equivalent: %.1f\n", celsius);return 0;}
```

Layout of a C Program

- The whole program can't be put on one line, because each preprocessing directive requires a separate line.
- Compressing programs in this fashion isn't a good idea.
- In fact, adding spaces and blank lines to a program can make it easier to read and understand.

Layout of a C Program

- C allows any amount of space—blanks, tabs, and new-line characters—between tokens.
- Consequences for program layout:
 - *Statements can be divided* over any number of lines.
 - *Space between tokens* (such as before and after each operator, and after each comma) makes it easier for the eye to separate them.
 - *Indentation* can make nesting easier to spot.
 - *Blank lines* can divide a program into logical units.

Layout of a C Program

- Although extra spaces can be added between tokens, it's not possible to add space within a token without changing the meaning of the program or causing an error.
- Writing

```
fl oat fahrenheit, celsius;  /*** WRONG ***/
```

or

```
fl
```

```
oat fahrenheit, celsius;      /*** WRONG ***/
```

produces an error when the program is compiled.

Layout of a C Program

- Putting a space inside a string literal is allowed, although it changes the meaning of the string.
- Putting a new-line character in a string (splitting the string over two lines) is illegal:

```
printf("To C, or not to C:  
that is the question.\n");  
    /** WRONG **/
```
