

# Representations of Regular Languages

COMPSCI 3331

# Outline

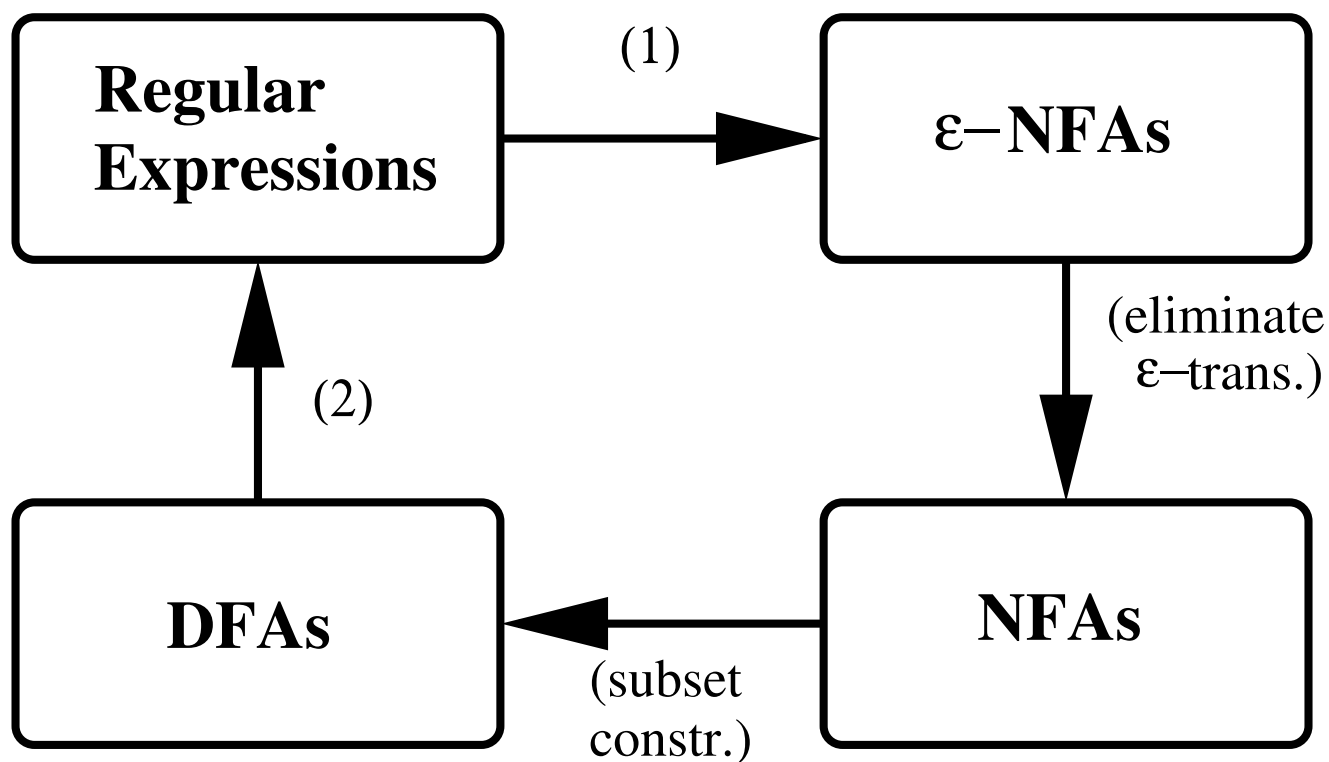

- ▶ Equivalence of Regular Expressions, NFAs, DFAs and  $\varepsilon$ -NFAs.
- ▶ Regular Expressions to  $\varepsilon$ -NFAs.
- ▶ DFAs to Regular Expressions.

# What do we already know?

- ▶ Every DFA is an NFA.
- ▶ How to convert an NFA to a DFA
  - ▶ subset construction
  - ▶ can go from  $n$  to  $2^n$  states.
- ▶ How to remove  $\varepsilon$ -transitions,
  - ▶ convert an  $\varepsilon$ -NFA to an NFA
  - ▶ number of states stays the same.

What about regular expressions?

# Representations of Regular Languages

# From RE to $\varepsilon$ -NFA

- ▶ **GOAL:** For every regular expression  $r$  define an  $\varepsilon$ -NFA  $M_r$ .
- ▶ Since regular expressions are defined recursively, the translation will be recursive.

Remember: Regular expressions are defined as:

- ▶  $\varepsilon, \emptyset, a$  for all  $a \in \Sigma$ .
- ▶  $r_1 + r_2, r_1 r_2$  and  $r_1^*$  for any regular expressions  $r_1, r_2$ .

# Intuitive conversion: RE to $\epsilon$ -NFA

Convert  $a^*(cb)^*$  to an  $\epsilon$ -NFA.

# From RE to $\varepsilon$ -NFA

We translate  $r$  to a  $\varepsilon$ -NFA  $M_r$  with:

- ▶ only one final state.
- ▶ start state different from the final state.
- ▶ no transitions leaving the only final state.
- ▶ no transitions entering the initial state.

# From RE to $\epsilon$ -NFA: Base Cases

Base cases:  $\emptyset$ ,  $\epsilon$  and  $a$  for all  $a \in \Sigma$ .

$r = \epsilon$

$r = a$

$r = \emptyset$

# From RE to $\epsilon$ -NFA: Union

# From RE to $\epsilon$ -NFA: Concatenation

# From RE to $\epsilon$ -NFA: Kleene Star

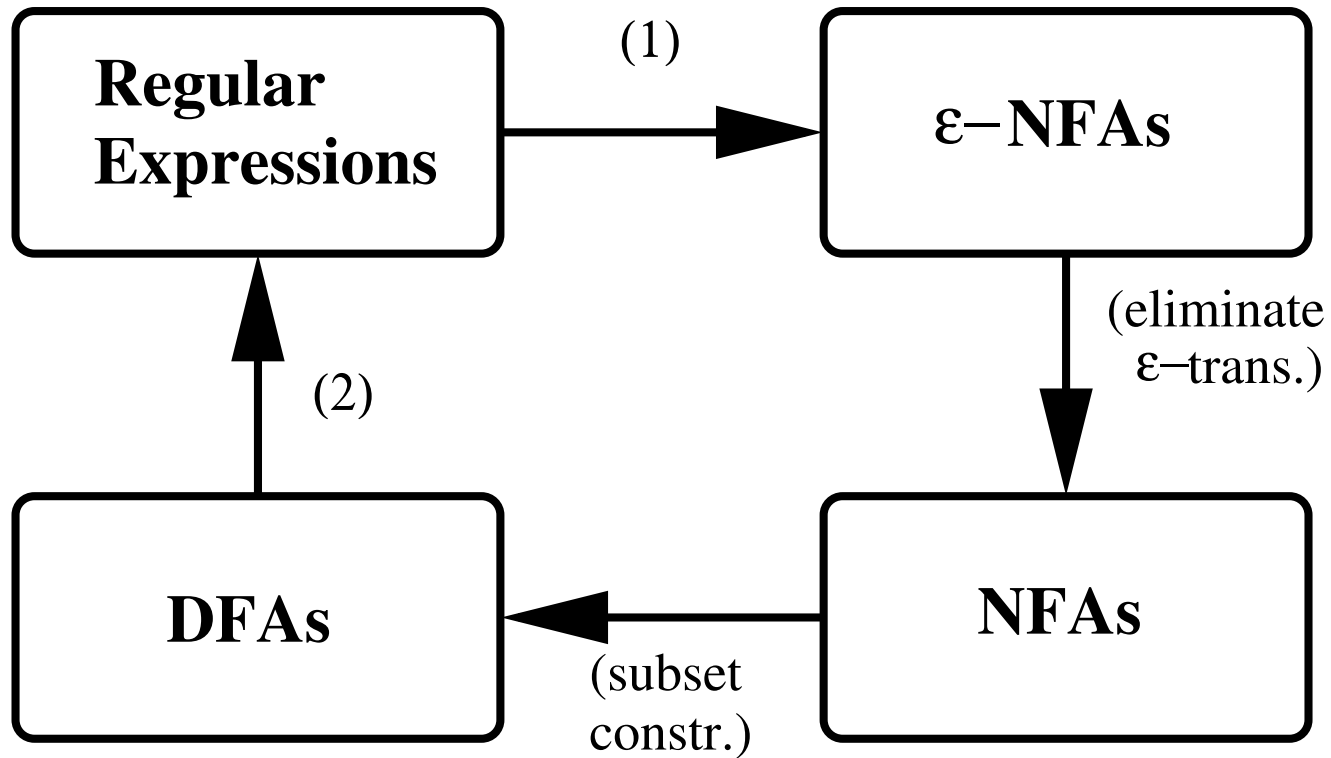

## From RE to $\varepsilon$ -NFA

**Theorem.** Let  $r$  be a regular expression and let  $M_r$  be the  $\varepsilon$ -NFA we get from applying the previous rules. Then  $L(r) = L(M_r)$ .

**Proof.** By structural induction.

# Conversion

# From DFA to RE (1 of 7)

- ▶ MAIN IDEA: Paths through a DFA correspond to parts of a regular expression for that DFA.
- ▶ State Elimination method: eliminate states one-by-one until we get a regular expression for the entire machine.

## From DFA to RE (2 of 7)

Consider an arbitrary state  $q$  of a DFA. What's going on at  $q$ ?

What words take us from  $r_i$  to  $s_j$  (for arbitrary  $1 \leq i \leq n$  and  $1 \leq j \leq m$ )?

## From DFA to RE (3 of 7)

Focus on one of the  $r_i$  and one of the  $s_j$ :

## From DFA to RE (4 of 7)

**MAIN IDEA:** we can replace the transitions with one transition labelled  $a_i(c_1 + \dots + c_t)^*b_j$ .

## From DFA to RE (5 of 7)

- ▶ Everything in the previous argument applies to **regular expressions** on transitions and not just letters.
- ▶ Apply the replacement to each (incoming, outgoing) transition pair before removing a state.
- ▶ Repeatedly apply removal process to states until we get a regular expression for the DFA.

## From DFA to RE (6 of 7)

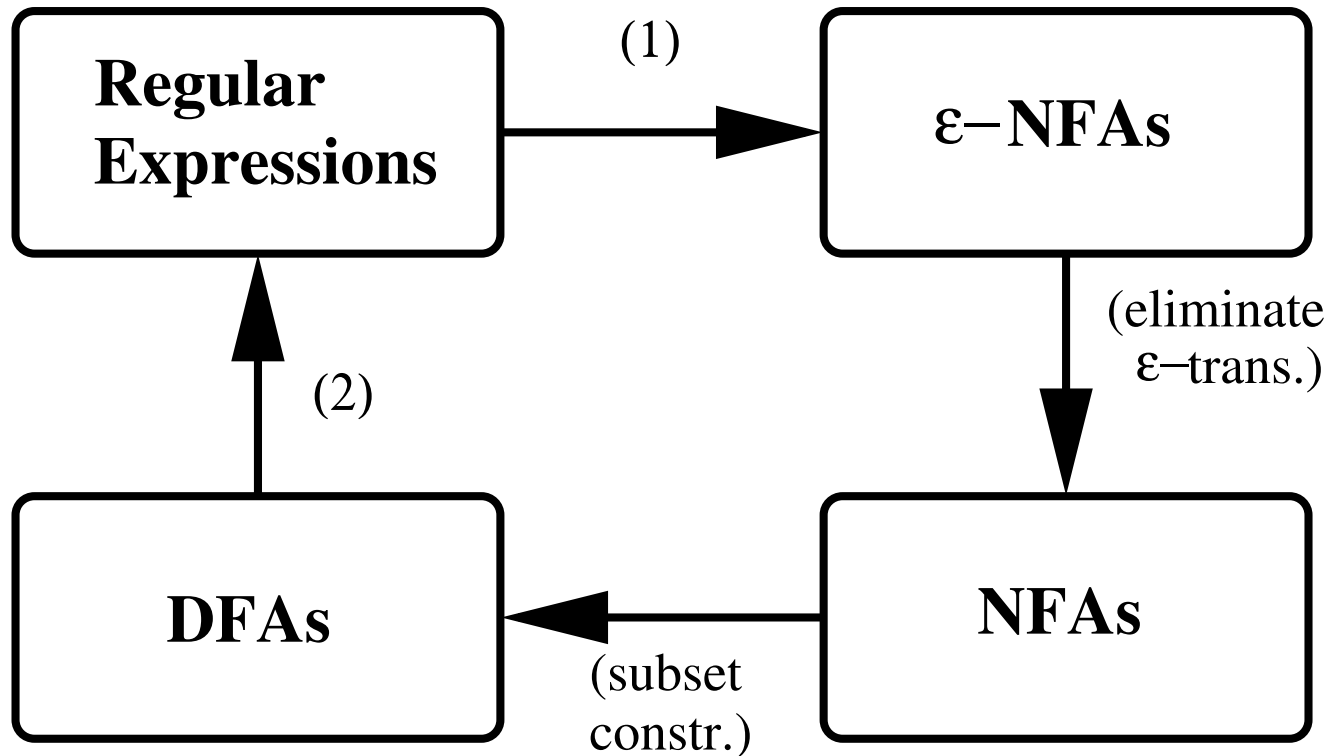

Replace multiple transitions from state  $q_1$  to  $q_2$  with one regular expression.

# From DFA to RE (7 of 7)

- ▶ Some pre-processing before beginning:
  - ▶ add a new start state and connect it to the old start state by an  $\varepsilon$ -transition
  - ▶ add a new final state and make all old final states point to it with an  $\varepsilon$ -transition
- ▶ Gives us states that won't be eliminated during the process.
- ▶ Eliminate any state which is not initial or final. At the end, read the regular expression for the DFA.

# Representations Summary

- (1) recursive translation of regular expressions to  $\epsilon$ -NFAs.
- (2) state elimination method.

# Representations of Regular Languages: Summary

**Theorem.** For every regular expression  $r$  there exists a DFA  $M$  such that  $L(r) = L(M)$ . For every DFA  $M$ , there exists a regular expression  $r$  such that  $L(M) = L(r)$ .
