ECON3102-005
Chapter 6: Economic growth: The Solow growth model (Part 1)

Neha Bairoliya

Spring 2014

Motivations

- Why do countries grow? Why are there poor countries? Why are there rich countries? Can poor countries be rich? If they cannot, why? If they can, why are they still poor?

Motivations

- Why do countries grow? Why are there poor countries? Why are there rich countries? Can poor countries be rich? If they cannot, why? If they can, why are they still poor?

- As Robert Lucas put it, "Once you start thinking about growth, its hard to think about anything else."

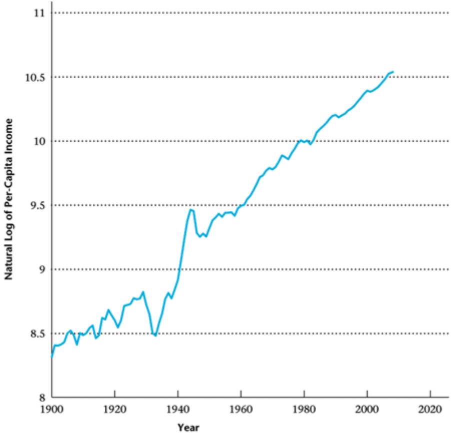
Motivations

- Why do countries grow? Why are there poor countries? Why are there rich countries? Can poor countries be rich? If they cannot, why? If they can, why are they still poor?

- As Robert Lucas put it, "Once you start thinking about growth, its hard to think about anything else."

- We'll use the framework we have learned and try to get some answers to the questions above. Now, there are some empirical facts that could help to motivate the discussion.

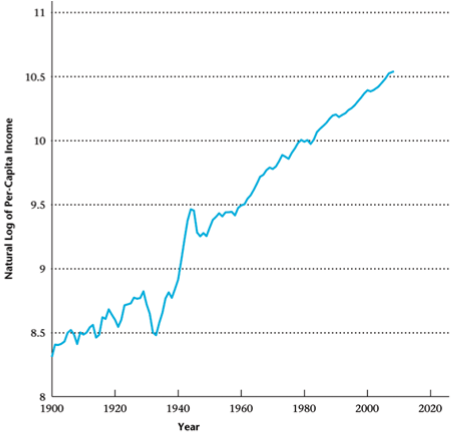
Observations



Source: Bureau of Economic Analysis, Department of Commerce and Romer, C. 1989. "The Prewar Business Cycle

Observations

- Before the industrial revolution, standards of living differed little over time and across countries.



Source: Bureau of Economic Analysis, Department of Commerce and Romer, C. 1989. "The Prewar Business Cycle

Observations

- Before the industrial revolution, standards of living differed little over time and across countries.
- Since the industrial revolution, per capita income growth has been sustained in the richest countries. In the US, average annual growth in per capita income has been about 2% since 1869.

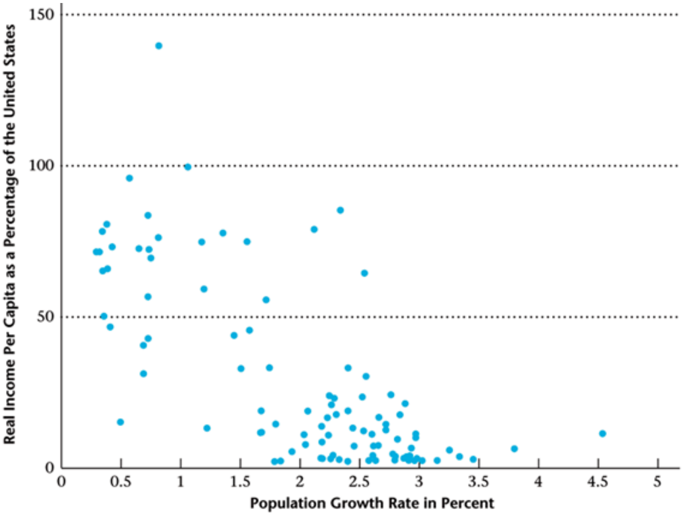
Observations



Source: A. Heston, R. Summers, and B. Aten, *Penn World Table Version 6.1*, Center for International Comparisons

Observations

- There is a negative correlation between the population growth rate and output per worker across countries.

The Solow Growth Model

First, consider the consumers in the economy. We'll add some dynamics here, as we analyze the economy in terms of the current and future periods. We also throw in some assumptions:

The Solow Growth Model

First, consider the consumers in the economy. We'll add some dynamics here, as we analyze the economy in terms of the current and future periods. We also throw in some assumptions:

- Population N grows at an exogenous rate n, following the equation

$$N' = (1+n)N, \quad \forall n > 1.$$

The Solow Growth Model

First, consider the consumers in the economy. We'll add some dynamics here, as we analyze the economy in terms of the current and future periods. We also throw in some assumptions:

- Population N grows at an exogenous rate n, following the equation

$$N' = (1 + n)N, \quad \forall n > 1.$$

- In each period, the consumer has one unit of time available. Consumers do not value leisure, so labor supply equals one. Then, the population equals the labor force: N represents both the number of workers and the population, and n is its growth rate.

The Solow Growth Model

First, consider the consumers in the economy. We'll add some dynamics here, as we analyze the economy in terms of the current and future periods. We also throw in some assumptions:

- Population N grows at an exogenous rate n, following the equation

$$N' = (1 + n)N, \quad \forall n > 1.$$

- In each period, the consumer has one unit of time available. Consumers do not value leisure, so labor supply equals one. Then, the population equals the labor force: N represents both the number of workers and the population, and n is its growth rate.

- There is no government; consequently, no taxes.

The Solow Growth Model (cont'd)

- Consumers receive Y, current real output, as income. They face the decision of how much of current income to save and how much to consume. We assume they consume a constant fraction of income:

$$C = (1 - s)Y, \quad s < 1,$$

where C is current consumption, s the savings rate, and current savings are $S = sY$.

The Solow Growth Model (cont'd)

Consider the representative firm.

- Output is produced by a representative firm, according to the production function

$$Y = zF(K, N), \tag{1}$$

which satisfies all the assumptions of Chapter 4.

The Solow Growth Model (cont'd)

Consider the representative firm.

- Output is produced by a representative firm, according to the production function

$$Y = zF(K, N), \tag{1}$$

  which satisfies all the assumptions of Chapter 4.

- Since it is CRS, dividing (1) by N gives

$$\frac{Y}{N} = zF(\frac{K}{N}, \frac{N}{N}) = zF(\frac{K}{N}, 1) \tag{2}$$

The Solow Growth Model (cont'd)

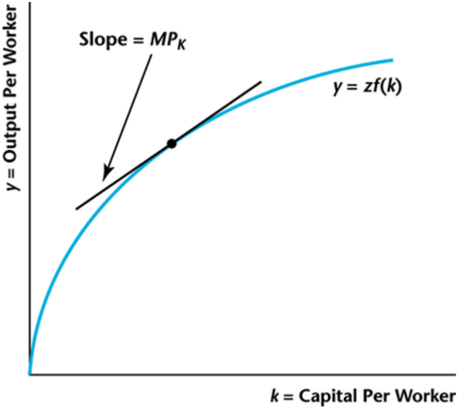
Consider the representative firm.

- Output is produced by a representative firm, according to the production function
$$Y = zF(K, N), \tag{1}$$
which satisfies all the assumptions of Chapter 4.

- Since it is CRS, dividing (1) by N gives
$$\frac{Y}{N} = zF(\frac{K}{N}, \frac{N}{N}) = zF(\frac{K}{N}, 1) \tag{2}$$

- Here we let $\frac{Y}{N}$ be output per worker, and $\frac{K}{N}$ capital per worker. Then (2) tells that the output per worker depends on the capital per worker.

The Solow Growth Model (cont'd)



- Rewrite (2) as

$$y = zf(k), \tag{3}$$

where $y = Y/N$, $k = K/N$, $f(k) = F(k, 1)$.

The Solow Growth Model (cont'd)

- Finally, let's add a depreciation rate to the production side.

The Solow Growth Model (cont'd)

- Finally, let's add a depreciation rate to the production side.
- Here, depreciation is denoted by d, where $0 < d < 1$.

The Solow Growth Model (cont'd)

- Finally, let's add a depreciation rate to the production side.
- Here, depreciation is denoted by d, where $0 < d < 1$.
- Now we can talk about dynamics. Given the depreciation rate, the capital stock changes over time according to

$$K' = (1 - d)K + I,$$

where I denotes investment.

The Solow Growth Model (cont'd)

Next we need to fit all this into a competitive equilibrium framework so that our ideas are consistent.

In this economy there are two markets: labor and assets.

The Solow Growth Model (cont'd)

Next we need to fit all this into a competitive equilibrium framework so that our ideas are consistent.

In this economy there are two markets: labor and assets.

- In the labor market, current consumption goods are traded for current labor.

The Solow Growth Model (cont'd)

Next we need to fit all this into a competitive equilibrium framework so that our ideas are consistent.

In this economy there are two markets: labor and assets.

- In the labor market, current consumption goods are traded for current labor.
- In the assets market, current consumption goods are traded for capital.

The Solow Growth Model (cont'd)

Next we need to fit all this into a competitive equilibrium framework so that our ideas are consistent.

In this economy there are two markets: labor and assets.

- In the labor market, current consumption goods are traded for current labor.
- In the assets market, current consumption goods are traded for capital.
- Capital is the asset in this economy, and consumers save by accumulating it.

The Solow Growth Model (cont'd)

- Note that the labor market clears at the inelastic supply of labor, N. (It follows that w adjusts automatically.)

The Solow Growth Model (cont'd)

- Note that the labor market clears at the inelastic supply of labor, N. (It follows that w adjusts automatically.)

- Let S be the aggregate amount of savings in the current period. Then, the capital market is in equilibrium if $S = I$; since $S = Y - C$, this can be expressed as:

$$Y = C + I.$$

The Solow Growth Model (cont'd)

- Note that the labor market clears at the inelastic supply of labor, N. (It follows that w adjusts automatically.)

- Let S be the aggregate amount of savings in the current period. Then, the capital market is in equilibrium if $S = I$; since $S = Y - C$, this can be expressed as:

$$Y = C + I.$$

- Substituting for I and C from equations, $K' = (1-d)K + I$ and $C = (1-s)Y$, gives

$$Y = (1-s)Y + K' - (1-d)K$$

$$K' = sY + (1-d)K. \tag{5}$$

The Solow Growth Model (cont'd)

- Note that the labor market clears at the inelastic supply of labor, N. (It follows that w adjusts automatically.)

- Let S be the aggregate amount of savings in the current period. Then, the capital market is in equilibrium if $S = I$; since $S = Y - C$, this can be expressed as:

$$Y = C + I.$$

- Substituting for I and C from equations, $K' = (1-d)K + I$ and $C = (1-s)Y$, gives

$$Y = (1-s)Y + K' - (1-d)K$$

$$K' = sY + (1-d)K. \tag{5}$$

- Equation (5) says that future capital equals the amount of savings plus capital left over from the current period that has not depreciated.

The Solow Growth Model (cont'd)

- Using equations, $Y = zF(K, N)$ and $K' = sY + (1-d)K$, we have

$$K' = szF(K, N) + (1-d)K.$$

The Solow Growth Model (cont'd)

- Using equations, $Y = zF(K, N)$ and $K' = sY + (1-d)K$, we have

$$K' = szF(K, N) + (1-d)K.$$

- We can divide by N to express in per worker terms

$$\frac{K'}{N} = szF(\frac{K}{N}, 1) + (1-d)\frac{K}{N},$$

multiplying the first term by $1 = N'/N'$

$$\frac{K'}{N}\frac{N'}{N'} = szF(\frac{K}{N}, 1) + (1-d)\frac{K}{N},$$

The Solow Growth Model (cont'd)

- Using equations, $Y = zF(K, N)$ and $K' = sY + (1-d)K$, we have

$$K' = szF(K, N) + (1-d)K.$$

- We can divide by N to express in per worker terms

$$\frac{K'}{N} = szF(\frac{K}{N}, 1) + (1-d)\frac{K}{N},$$

multiplying the first term by $1 = N'/N'$

$$\frac{K'}{N}\frac{N'}{N'} = szF(\frac{K}{N}, 1) + (1-d)\frac{K}{N},$$

- which is

$$k'(1+n) = szf(k) + (1-d)k.$$

The Solow Growth Model (cont'd)

- Using equations, $Y = zF(K, N)$ and $K' = sY + (1 - d)K$, we have

$$K' = szF(K, N) + (1 - d)K.$$

- We can divide by N to express in per worker terms

$$\frac{K'}{N} = szF(\frac{K}{N}, 1) + (1 - d)\frac{K}{N},$$

multiplying the first term by $1 = N'/N'$

$$\frac{K'}{N}\frac{N'}{N'} = szF(\frac{K}{N}, 1) + (1 - d)\frac{K}{N},$$

- which is

$$k'(1 + n) = szf(k) + (1 - d)k.$$

- Dividing across by $(1 + n)$ gives the key equation of the model:

$$k' = \frac{szf(k)}{1+n} + \frac{(1-d)k}{1+n} \qquad (*)$$

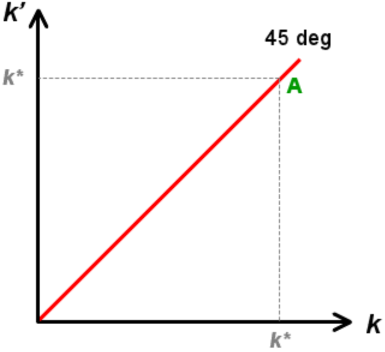
Steady States

We want to find the steady state of the model. This is, the point at which $k' = k = k^*$.

Steady States

We want to find the steady state of the model. This is, the point at which $k' = k = k^*$.

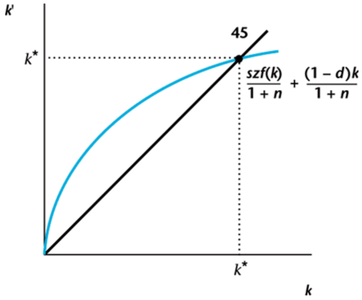
- Note that when we graph in $k'k$ space, any point that crosses the 45 degree line satisfies $k' = k$.



Steady State in the Solow Growth Model

Recall equation (*):

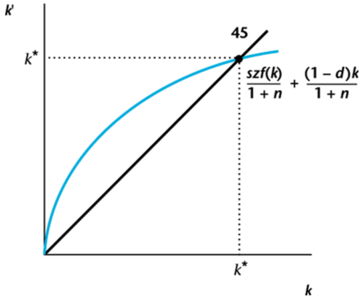
$$k' = \frac{szf(k)}{1+n} + \frac{(1-d)k}{1+n} \qquad (*)$$



Steady State in the Solow Growth Model

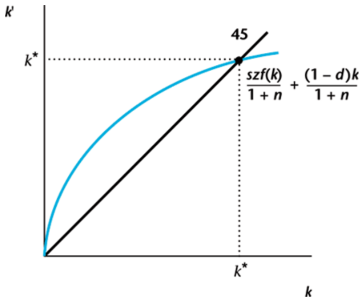
Recall equation (*):

$$k' = \frac{szf(k)}{1+n} + \frac{(1-d)k}{1+n} \qquad (*)$$



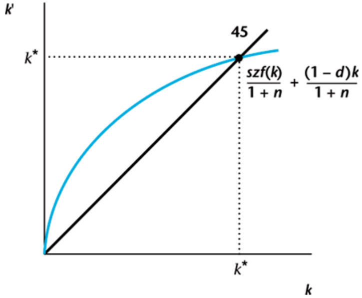
- At the steady state, $k = k^*$ and $k' = k^*$; k^* is the equilibrium level of capital in the economy.

Steady State in the Solow Growth Model



- Suppose $k < k^*$. Then $k' > k$, and the capital stock increases from the current to the future period, until $k = k^*$.

Steady State in the Solow Growth Model



- Suppose $k < k^*$. Then $k' > k$, and the capital stock increases from the current to the future period, until $k = k^*$.
- Here, current investment is relatively large with respect to depreciation and labor force growth.

Steady State Growth Rates

- What is the growth rate of k^*?

Steady State Growth Rates

- What is the growth rate of k^*?
- The answer: zero.

Steady State Growth Rates

- What is the growth rate of k^*?
- The answer: zero.
- Why? Since its a steady state, it wont move from there.

Steady State Growth Rates

- What is the growth rate of k^*?
- The answer: zero.
- Why? Since its a steady state, it wont move from there.
- Another question: What is the growth rate of y^*?

Steady State Growth Rates

- What is the growth rate of k^*?
- The answer: zero.
- Why? Since its a steady state, it wont move from there.
- Another question: What is the growth rate of y^*?
- The answer: zero.

Steady State Growth Rates

- What is the growth rate of k^*?
- The answer: zero.
- Why? Since its a steady state, it wont move from there.
- Another question: What is the growth rate of y^*?
- The answer: zero.
- Why? Since $k = k^*$ in the long run, output per worker is constant at $y^* = zf(k^*)$.

Steady State Growth Rates

- What is the growth rate of k^*?
- The answer: zero.
- Why? Since its a steady state, it wont move from there.
- Another question: What is the growth rate of y^*?
- The answer: zero.
- Why? Since $k = k^*$ in the long run, output per worker is constant at $y^* = zf(k^*)$.
- So, theres no growth in here? Are we forgetting something?

Steady State Growth Rates

There is growth in this economy! In the long run, when $k = k^*$, all real aggregate quantities grow at a rate n. Why?

- The aggregate quantity of capital is $K = k^* N$. Since k^* is constant and N grows at a rate n, K should grow at a rate n.

Steady State Growth Rates

There is growth in this economy! In the long run, when $k = k^*$, all real aggregate quantities grow at a rate n. Why?

- The aggregate quantity of capital is $K = k^* N$. Since k^* is constant and N grows at a rate n, K should grow at a rate n.

- Aggregate real output is $Y = y * N = zf(k^*)N$, hence Y also grows at a rate n.

Steady State Growth Rates

There is growth in this economy! In the long run, when $k = k^*$, all real aggregate quantities grow at a rate n. Why?

- The aggregate quantity of capital is $K = k^* N$. Since k^* is constant and N grows at a rate n, K should grow at a rate n.
- Aggregate real output is $Y = y * N = zf(k^*)N$, hence Y also grows at a rate n.
- Consumption and investment follow the same logic:

$$I = sY = szf(k^*)N,$$

$$C = (1 - s)Y = (1 - s)zf(k^*)N.$$

Steady State Growth Rates

There is growth in this economy! In the long run, when $k = k^*$, all real aggregate quantities grow at a rate n. Why?

- The aggregate quantity of capital is $K = k^* N$. Since k^* is constant and N grows at a rate n, K should grow at a rate n.

- Aggregate real output is $Y = y * N = zf(k^*)N$, hence Y also grows at a rate n.

- Consumption and investment follow the same logic:

$$I = sY = szf(k^*)N,$$

$$C = (1 - s)Y = (1 - s)zf(k^*)N.$$

- In this way, the Solow growth model is an exogenous growth model.
