Chapter 10

Program Organization

Local Variables

• A variable declared in the body of a function is said to be *local* to the function:

Local Variables

- Default properties of local variables:
 - Automatic storage duration. Storage is "automatically" allocated when the enclosing function is called and deallocated when the function returns.
 - Block scope. A local variable is visible from its point of declaration to the end of the enclosing function body.

Local Variables

• Since C99 doesn't require variable declarations to come at the beginning of a function, it's possible for a local variable to have a very small scope:

Static Local Variables

- Including static in the declaration of a local variable causes it to have *static storage duration*.
- A variable with static storage duration has a permanent storage location, so it retains its value throughout the execution of the program.
- Example:

```
void f(void)
{
  static int i;  /* static local variable */
  ...
}
```

• A static local variable still has block scope, so it's not visible to other functions.

Parameters

- Parameters have the same properties—automatic storage duration and block scope—as local variables.
- Each parameter is initialized automatically when a function is called (by being assigned the value of the corresponding argument).

External Variables

- Passing arguments is one way to transmit information to a function.
- Functions can also communicate through *external variables*—variables that are declared outside the body of any function.
- External variables are sometimes known as *global* variables.

External Variables

- Properties of external variables:
 - Static storage duration
 - File scope
- Having *file scope* means that an external variable is visible from its point of declaration to the end of the enclosing file.

- To illustrate how external variables might be used, let's look at a data structure known as a *stack*.
- A stack, like an array, can store multiple data items of the same type.
- The operations on a stack are limited:
 - **Push** an item (add it to one end—the "stack top")
 - Pop an item (remove it from the same end)
- Examining or modifying an item that's not at the top of the stack is forbidden.

- One way to implement a stack in C is to store its items in an array, which we'll call contents.
- A separate integer variable named top marks the position of the stack top.
 - When the stack is empty, top has the value 0.
- To *push* an item: Store it in contents at the position indicated by top, then increment top.
- To pop an item: Decrement top, then use it as an index into contents to fetch the item that's being popped.

- The following program fragment declares the contents and top variables for a stack.
- It also provides a set of functions that represent stack operations.
- All five functions need access to the top variable, and two functions need access to contents, so contents and top will be external.

```
#include <stdbool.h> /* C99 onlv */
#define STACK SIZE 100
/* external variables */
int contents[STACK SIZE];
int top = 0;
void make_empty(void)
 top = 0;
bool is empty (void)
  return top == 0;
```

```
bool is_full(void)
  return top == STACK SIZE;
void push(int i)
  if (is full()
    stack_overflow();
  else
    contents[top++] = i;
int pop(void)
  if (is_empty())
    stack_underflow();
  else
    return contents[--top];
```

- External variables are convenient when many functions must share a variable or when a few functions share a large number of variables.
- In most cases, it's better for functions to communicate through parameters rather than by sharing variables:
 - If we change an external variable during program maintenance (by altering its type, say), we'll need to check every function in the same file to see how the change affects it.
 - If an external variable is assigned an incorrect value, it may be difficult to identify the guilty function.
 - Functions that rely on external variables are hard to reuse in other programs.

- Don't use the same external variable for different purposes in different functions.
- Suppose that several functions need a variable named i to control a for statement.
- Instead of declaring i in each function that uses it, some programmers declare it just once at the top of the program.
- This practice is misleading; someone reading the program later may think that the uses of i are related, when in fact they're not.

- Make sure that external variables have meaningful names.
- Local variables don't always need meaningful names: it's often hard to think of a better name than i for the control variable in a for loop.

- Making variables external when they should be local can lead to some rather frustrating bugs.
- Code that is supposed to display a 10×10 arrangement of asterisks:

```
int i;
void print_one_row(void)
{
  for (i = 1; i <= 10; i++)
     printf("*");
}

void print_all_rows(void)
{
  for (i = 1; i <= 10; i++) {
     print_one_row();
     printf("\n");
  }
}</pre>
```

• Instead of printing 10 rows, print_all_rows prints only one.

Program: Guessing a Number

• The guess.c program generates a random number between 1 and 100, which the user attempts to guess in as few tries as possible:

Guess the secret number between 1 and 100.

```
A new number has been chosen.

Enter guess: 55

Too low; try again.

Enter guess: 65

Too high; try again.

Enter guess: 60

Too high; try again.

Enter guess: 58
```

You won in 4 quesses!

Program: Guessing a Number

```
Play again? (Y/N) \underline{y}
A new number has been chosen. Enter guess: \underline{78}
Too high; try again. Enter guess: \underline{34}
You won in 2 guesses! Play again? (Y/N) \underline{n}
```

- Tasks to be carried out by the program:
 - Initialize the random number generator
 - Choose a secret number
 - Interact with the user until the correct number is picked
- Each task can be handled by a separate function.

guess.c

```
/* Asks user to guess a hidden number */
#include <stdio.h>
#include <stdlib.h>
#include <time.h>
#define MAX NUMBER 100
/* external variable */
int secret_number;
/* prototypes */
void initialize number generator(void);
void choose_new_secret_number(void);
void read_guesses(void);
```

```
int main(void)
  char command;
 printf("Guess the secret number between 1 and d.\n\n",
         MAX NUMBER);
  initialize_number_generator();
 do {
    choose_new_secret_number();
   printf("A new number has been chosen.\n");
   read quesses();
   printf("Play again? (Y/N) ");
    scanf(" %c", &command);
   printf("\n");
  } while (command == 'y' || command == 'Y');
 return 0;
```

```
/****************
  initialize number generator: Initializes the random
                       number generator using
*
                       the time of day.
void initialize_number_generator(void)
 srand((unsigned) time(NULL));
/****************
 choose new secret number: Randomly selects a number
                     between 1 and MAX NUMBER and
*
*
                     stores it in secret number.
*************************************
void choose_new_secret_number(void)
 secret number = rand() % MAX NUMBER + 1;
```

```
/***************
  read_quesses: Repeatedly reads user quesses and tells
              the user whether each guess is too low,
 *
              too high, or correct. When the guess is
                                                  *
              correct, prints the total number of
              quesses and returns.
void read quesses(void)
 int guess, num guesses = 0;
 for (;;) {
   num quesses++;
   printf("Enter quess: ");
   scanf("%d", &quess);
   if (quess == secret_number) {
     printf("You won in %d quesses!\n\n", num_quesses);
     return;
   } else if (quess < secret number)</pre>
     printf("Too low; try again.\n");
   else
     printf("Too high; try again.\n");
```

Program: Guessing a Number

- Although guess.c works fine, it relies on the external variable secret_number.
- By altering choose_new_secret_number and read_guesses slightly, we can move secret_number into the main function.
- The new version of guess.c follows, with changes in **bold**.

guess2.c

```
/* Asks user to guess a hidden number */
#include <stdio.h>
#include <stdlib.h>
#include <time.h>

#define MAX_NUMBER 100

/* prototypes */
void initialize_number_generator(void);
int new_secret_number(void);
void read_guesses(int secret_number);
```

```
int main(void)
  char command;
  int secret number;
 printf("Guess the secret number between 1 and %d.\n\n",
         MAX NUMBER);
  initialize_number_generator();
 do {
    secret number = new secret number();
   printf("A new number has been chosen.\n");
   read quesses (secret number);
   printf("Play again? (Y/N) ");
    scanf(" %c", &command);
   printf("\n");
  } while (command == 'y' || command == 'Y');
 return 0;
```

```
/****************
 initialize number generator: Initializes the random
                    number generator using
*
                    the time of day.
void initialize_number_generator(void)
 srand((unsigned) time(NULL));
/*****************
* new secret number: Returns a randomly chosen number
              between 1 and MAX NUMBER.
                                     *
int new secret number(void)
 return rand() % MAX NUMBER + 1;
```

```
/***************
  read_quesses: Repeatedly reads user quesses and tells
              the user whether each guess is too low,
 *
              too high, or correct. When the guess is
                                                   *
              correct, prints the total number of
              quesses and returns.
void read quesses(int secret number)
 int quess, num quesses = 0;
 for (;;) {
   num quesses++;
   printf("Enter quess: ");
   scanf("%d", &quess);
   if (quess == secret_number) {
     printf("You won in %d quesses!\n\n", num_quesses);
     return;
   } else if (quess < secret number)</pre>
     printf("Too low; try again.\n");
   else
     printf("Too high; try again.\n");
```

Blocks

• In Section 5.2, we encountered compound statements of the form

```
{ statements }
```

• C allows compound statements to contain declarations as well as statements:

```
{ declarations statements }
```

• This kind of compound statement is called a *block*.

Blocks

• Example of a block:

```
if (i > j) {
    /* swap values of i and j */
    int temp = i;
    i = j;
    j = temp;
}
```

Blocks

- By default, the storage duration of a variable declared in a block is automatic: storage for the variable is allocated when the block is entered and deallocated when the block is exited.
- The variable has block scope; it can't be referenced outside the block.
- A variable that belongs to a block can be declared static to give it static storage duration.

Blocks

- The body of a function is a block.
- Blocks are also useful inside a function body when we need variables for temporary use.
- Advantages of declaring temporary variables in blocks:
 - Avoids cluttering declarations at the beginning of the function body with variables that are used only briefly.
 - Reduces name conflicts.
- C99 allows variables to be declared anywhere within a block.

Scope

- In a C program, the same identifier may have several different meanings.
- C's scope rules enable the programmer (and the compiler) to determine which meaning is relevant at a given point in the program.
- The most important scope rule: When a declaration inside a block names an identifier that's already visible, the new declaration temporarily "hides" the old one, and the identifier takes on a new meaning.
- At the end of the block, the identifier regains its old meaning.

Scope

- In the example on the next slide, the identifier i has four different meanings:
 - In Declaration 1, i is a variable with static storage duration and file scope.
 - In Declaration 2, i is a parameter with block scope.
 - In Declaration 3, i is an automatic variable with block scope.
 - In Declaration 4, i is also automatic and has block scope.
- C's scope rules allow us to determine the meaning of i each time it's used (indicated by arrows).

```
int(i);
               /* Declaration 1 */
void f(int(i))
               /* Declaration 2 */
  i = 1;
void g(void)
  int(i) = 2; /* Declaration 3 */
  if (i > 0) {
              /* Declaration 4 */
    int(i);
void h(void)
  i = 5;
```

Organizing a C Program

- Major elements of a C program:
 - Preprocessing directives such as #include and #define
 - Type definitions
 - Declarations of external variables
 - Function prototypes
 - Function definitions

Organizing a C Program

- C imposes only a few rules on the order of these items:
 - A preprocessing directive doesn't take effect until the line on which it appears.
 - A type name can't be used until it's been defined.
 - A variable can't be used until it's declared.
- It's a good idea to define or declare every function prior to its first call.
 - C99 makes this a requirement.

Organizing a C Program

- There are several ways to organize a program so that these rules are obeyed.
- One possible ordering:
 - #include directives
 - #define directives
 - Type definitions
 - Declarations of external variables
 - Prototypes for functions other than main
 - Definition of main
 - Definitions of other functions

Organizing a C Program

- It's a good idea to have a boxed comment preceding each function definition.
- Information to include in the comment:
 - Name of the function
 - Purpose of the function
 - Meaning of each parameter
 - Description of return value (if any)
 - Description of side effects (such as modifying external variables)

- The poker.c program will classify a poker hand.
- Each card in the hand has a *suit* and a *rank*.
 - Suits: clubs, diamonds, hearts, spades
 - Ranks: two, three, four, five, six, seven, eight, nine, ten, jack, queen, king, ace
- Jokers are not allowed, and aces are high.
- After reading a hand of five cards, the program will classify the hand using the categories on the next slide.
- If a hand falls into two or more categories, the program will choose the best one.

- Categories (listed from best to worst):
 - straight flush (both a straight and a flush)
 - four-of-a-kind (four cards of the same rank)
 - full house (a three-of-a-kind and a pair)
 - flush (five cards of the same suit)
 - straight (five cards with consecutive ranks)
 - three-of-a-kind (three cards of the same rank)
 - two pairs
 - pair (two cards of the same rank)
 - high card (any other hand)

• For input purposes, ranks and suits will be single letters (upper- or lower-case):

Ranks: 2 3 4 5 6 7 8 9 t j q k a

Suits: c d h s

- Actions to be taken if the user enters an illegal card or tries to enter the same card twice:
 - Ignore the card
 - Issue an error message
 - Request another card
- Entering the number 0 instead of a card will cause the program to terminate.

• A sample session with the program:

```
Enter a card: 2s
Enter a card: 5s
Enter a card: 4s
Enter a card: 3s
Enter a card: 6s
Straight flush
```

```
Enter a card: 8c
Enter a card: as
Enter a card: 8c
Duplicate card; ignored.
Enter a card: 7c
Enter a card: ad
Enter a card: 3h
Pair
```

Program: Classifying a Poker Hand

```
Enter a card: 6s
Enter a card: d2
Bad card; ignored.
Enter a card: 2d
Enter a card: 9c
Enter a card: 4h
Enter a card: ts
High card
```

Enter a card: 0

- The program has three tasks:
 - Read a hand of five cards
 - Analyze the hand for pairs, straights, and so forth
 - Print the classification of the hand
- The functions read_cards, analyze_hand, and print_result will perform these tasks.
- main does nothing but call these functions inside an endless loop.

- The functions will need to share a fairly large amount of information, so we'll have them communicate through external variables.
- read_cards will store information about the hand into several external variables.
- analyze_hand will then examine these variables, storing its findings into other external variables for the benefit of print_result.

Program: Classifying a Poker Hand

• Program outline:

```
/* #include directives go here */
/* #define directives go here */
/* declarations of external variables go here */
/* prototypes */
void read_cards(void);
void analyze_hand(void);
void print_result(void);
```

```
/*****************
 main: Calls read cards, analyze hand, and print result *
     repeatedly.
int main(void)
 for (;;) {
  read cards();
  analyze hand();
  print_result();
/***************
 read cards:
        Reads the cards into external variables;
         checks for bad cards and duplicate cards.
void read cards(void)
```

```
/****************
  analyze hand: Determines whether the hand contains a
           straight, a flush, four-of-a-kind,
           and/or three-of-a-kind; determines the
           number of pairs; stores the results into
           external variables.
void analyze_hand(void)
/*****************
* print_result: Notifies the user of the result, using
*
           the external variables set by
           analyze_hand.
void print result(void)
```

- How should we represent the hand of cards?
- analyze_hand will need to know how many cards are in each rank and each suit.
- This suggests that we use two arrays, num_in_rank and num_in_suit.
 - num_in_rank[r] will be the number of cards with rank r.
 - num_in_suit[s] will be the number of cards with suit s.
- We'll encode ranks as numbers between 0 and 12.
- Suits will be numbers between 0 and 3.

- We'll also need a third array, card_exists, so that read_cards can detect duplicate cards.
- Each time read_cards reads a card with rank r and suit s, it checks whether the value of card_exists[r][s] is true.
 - If so, the card was previously entered.
 - If not, read_cards assigns true to card_exists[r][s].

- Both the read_cards function and the analyze_hand function will need access to the num_in_rank and num_in_suit arrays, so they will be external variables.
- The card_exists array is used only by read_cards, so it can be local to that function.
- As a rule, variables should be made external only if necessary.

poker.c

```
/* Classifies a poker hand */
#include <stdbool.h> /* C99 onlv */
#include <stdio.h>
#include <stdlib.h>
#define NUM RANKS 13
#define NUM SUITS 4
