Chapter One: Introduction

A SHORT INTRODUCTION TO HARDWARE, SOFTWARE, AND ALGORITHM DEVELOPMENT

Chapter Goals

- In this chapter you will earn:
 - About computer hardware, software and programming
 - How to write and execute your first Python program
 - How to diagnose and fix programming errors
 - How to use pseudocode to describe an algorithm

Computer Programs

- A computer program tells a computer the sequence of steps needed to complete a specific task
 - The program consists of a very large number of primitive (simple) instructions
- Computers can carry out a wide range of tasks because they can execute different programs
 - Each program is designed to direct the computer to work on a specific task

Programming:

• The act of designing, implementing, and testing computer programs

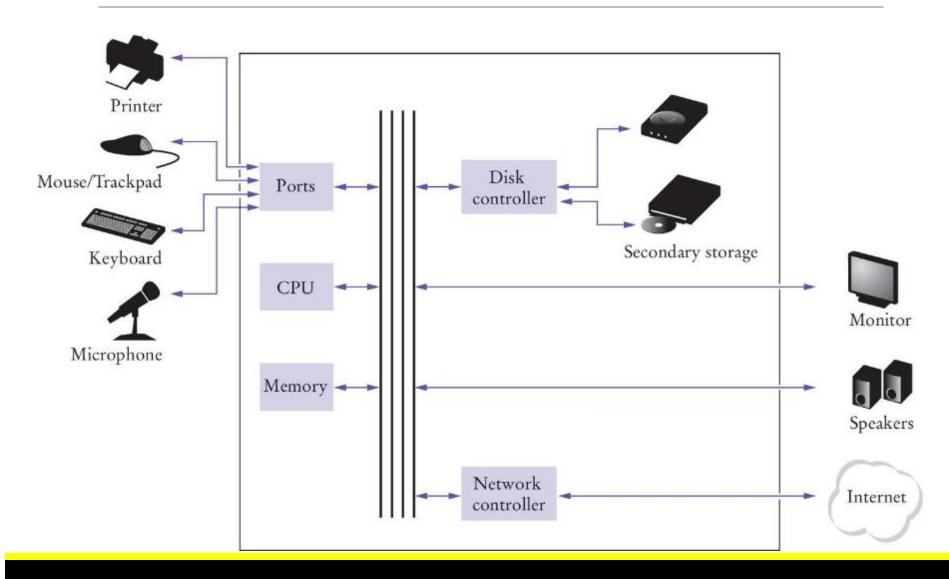

Hardware and Software

THE BUILDING BLOCKS THAT MAKE UP A COMPUTER

Hardware

- *Hardware* consists of the physical elements in a computer system.
 - Some very visible examples are the monitor, the mouse, external storage, and the keyboard.
- The central processing unit (CPU) performs program control and data processing
- Storage devices include memory (RAM) and secondary storage
 - Hard disk
 - Flash drives
 - CD/DVD drives
- Input / output devices allow the user to interact with the computer
 - Mouse, keyboard, printer, screen...

Simple View of a Computer's Components

The CPU

- The CPU has two components, the control unit and the arithmetic logic unit
- The control unit directs operation of the processor.
 - All computer resources are managed by the control unit.
 - It controls communication and co-ordination between input/output devices.
 - It reads and interprets instructions and determines the sequence for processing the data.
 - It provides timing and control signals
- The *arithmetic logic unit* contains the circuitry to perform calculations and do comparisons.
 - It is the workhorse portion of the computer and its job is to do precisely what the control unit tells it to do.

Storage

- There are two types of storage:
 - Primary Storage
 - Secondary Storage
- Primary storage is composed of memory chips: electronic circuits that can store data as long as it is provided electric power
- Secondary storage provides a slower, less expensive storage that is persistent: the data persists without electric power
- Computers store both data and programs
 - The data and program are located in secondary storage and loaded into memory when the program is executed

Memory

- A simple way to envision primary memory is a table of cells all the same size, one byte, and each containing a unique address beginning with 0.
 - The "typical" computer has a main memory ranging from 4 gigabytes (GB), to 32 GB.
- How big is a gigabyte?
 - A byte is 8 bits.
 - A kilobyte, KB, is 1024 bytes, or "about 1 thousand bytes."
 - A megabyte, MB, is 1,048,576 bytes, or "about 1 million bytes."
 - A *gigabyte*, GB, is 1,073,741,824 bytes or "about 1 billion bytes."

Executing a Program

- Program instructions and data (such as text, numbers, audio, or video) are stored in digital format
- When a program is started, it is brought into memory, where the CPU can read it.
- The CPU runs the program one instruction at a time.
 - The program may react to user input.
- The instructions and user input guide the program execution
 - The CPU reads data (including user input), modifies it, and writes it back to memory, the screen, or secondary storage.

Software

- **Software** is typically realized as an application program
 - Microsoft Word is an example of software
 - Computer Games are software
 - Operating systems and device drivers are also software
- Software
 - Software is a sequence of instructions and decisions implemented in some language and translated to a form that can be executed or run on the computer.
- Computers execute very basic instructions in rapid succession
 - The basic instructions can be grouped together to perform complex tasks
- Programming is the act of designing and implementing computer programs

Algorithms

Introduction to Algorithms

- If you want a computer to perform a task, you start by writing an algorithm
- An *Algorithm* is:
 - a sequence (the order mattering) of actions to take to accomplish the given task
 - An algorithm is like a recipe; it is a set of instructions written in a sequence that achieves a goal
- For complex problems software developers write an algorithm before they attempt to write a computer program
- Developing algorithms is a fundamental problem solving skill
 - It has uses in many fields outside of Computer Science

Algorithm: Formal Definition

An *algorithm* describes a sequence of steps that is:

- 1. Unambiguous
 - a. No "assumptions" are required to execute the algorithm
 - b. The algorithm uses precise instructions
- 2. Executable
 - a. The algorithm can be carried out in practice
- 3. Terminating
 - a. The algorithm will eventually come to an end, or halt

Problem Solving: Algorithm Design

- Algorithms are simply plans
 - Detailed plans that describe the steps to solve a specific problem
- You already know quite a few
 - Calculate the area of a circle
 - Find the length of the hypotenuse of a triangle
- Some problems are more complex and require more steps
 - Calculate PI to 100 decimal places
 - Calculate the trajectory of a missile

Bank Account Example

- Problem Statement:
 - You put \$10,000 into a bank account that earns 5 percent interest per year.
 How many years does it take for the account balance to be double the original?
- How would you solve it?
 - Manual method
 - Make a table
 - Add lines until done
 - Use a spreadsheet!
 - Write a formula
 - Per line, based on line above

year	balance	
0	10000	
1	10000.00 x 1.05 = 10500.00	
2	10500.00 x 1.05 = 11025.00	
3	11025.00 x 1.05 = 11576.25	
4	11576.25 x 1.05 = 12155.06	

Develop the algorithm steps

You put \$10,000 into a bank account that earns 5 percent interest per year.
 How many years does it take for the account balance to be double the original?

- Break it into steps
 - Start with a year value of 0 and a balance of \$10,000
 - Repeat the following while the balance is less than \$20,000
 - Add 1 to the year value
 - Multiply the balance by 1.05
 - (5% increase)

• Report the final year value as the answer

year	balance
0	10000
1	10500

balance

10000

year

14	19799.32
15	20789.28

Translate to pseudocode

- Pseudocode
 - Half-way between natural language and a programming language
- Modified Steps
 - Set the year value of 0
 - Set the balance to \$10,000
 - While the balance is less than \$20,000
 - Add 1 to the year value
 - Multiply the balance by 1.05
 - Report the final year value as the answer
- The pseudocode is easily translated into Python

Python and Programming Environments

The Python Language

- In the early 1990's, Guido van Rossum designed what would become the Python programming language
- Van Rossum was dissatisfied with the languages available
 - They were optimized to write large programs that executed quickly
- He needed a language that could not only be used to create programs quickly but also make them easy to modify
 - It was designed to have a much simpler and cleaner syntax than other popular languages such as Java, C and C++ (making it easier to learn)
 - Python is interpreted, making it easier to develop and test short programs
- Python programs are executed by the Python interpreter
 - The interpreter reads your program and executes it

Programming Environments

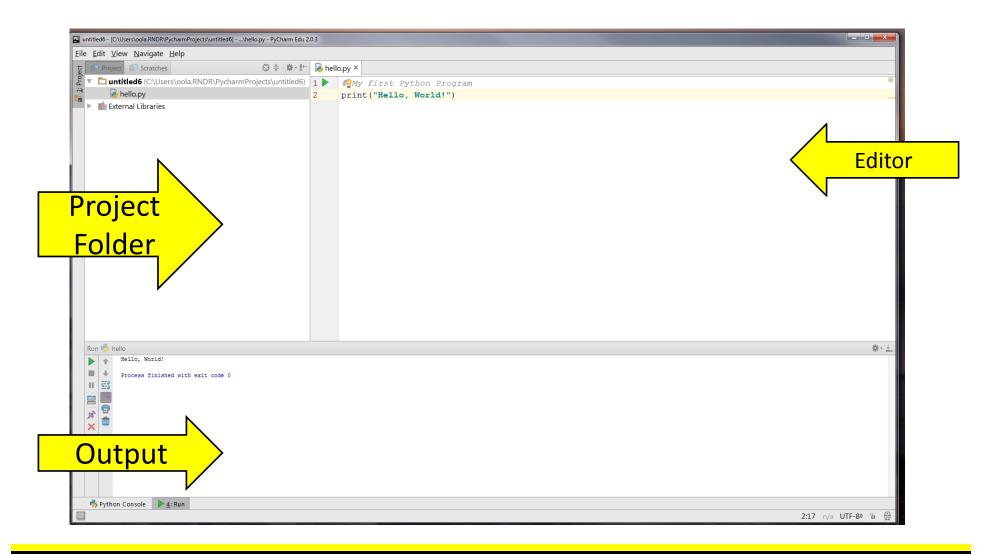

- There are several ways of creating a computer program
 - Using an Integrated Development Environment (IDE)
 - Using a text editor
- IDE vs. Interpreter
 - Python is the Interpreter
 - PyCharm is the IDE
- You should use the method you are most comfortable with.
 - In this class, I will use the **PyCharm Educational Version**

9/5/2019 21

IDE components

- The source code editor can help programming by:
 - Listing line numbers of code
 - Color lines of code (comments, text...)
 - Auto-indent source code
- Output window
- Debugger

PyCharm IDE

Your first program

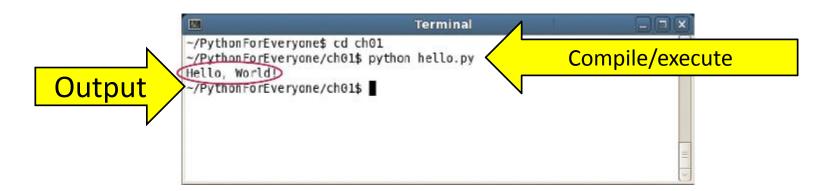

• Traditional 'Hello World' program in Python

```
1 # My first Python program.
2 print("Hello, World!")
3
```

- We will examine this program in the next section
 - Typing the program into your IDE would be good practice!
 - Be careful of spelling e.g., 'print' vs. 'primt'
 - PyTHon iS CaSe SeNsItiVe.

Text editor programming

- You can also use a simple text editor to write your source code
- Once saved as Hello.py, you can use a console window to:
 - Compile the program
 - Run the program

9/5/2019 25

Organize your work

- Your 'source code' is stored in .py files
- Create a folder for this course
- Create one folder per program inside the course folder
 - A program can consist of several .py files
- Be sure you know where your IDE stores your files
 - You need to be able to find you files

• Backup your files:

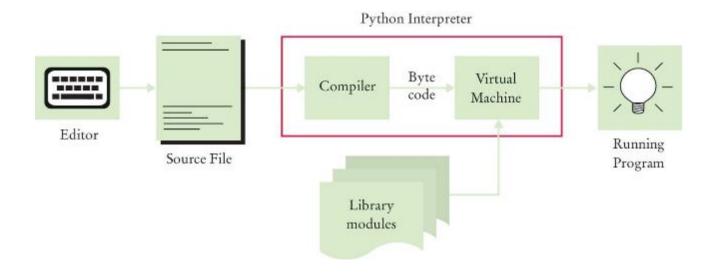

- To a USB flash drive
- To a network drive

Python interactive mode

- Like other languages you can write/save a complete Python program in a file and let the interpreter execute the instructions all at once.
- Alternatively you can run instructions one at a time using interactive mode.
 - It allows quick 'test programs' to be written.
 - Interactive mode allows you to write python statements directly in the console window

Source Code to a Running Program

- The compiler reads your program and generates byte code instructions (simple instructions for the Python Virtual machine)
 - The Python Virtual machine is a program that is similar to the CPU of your computer
 - Any necessary libraries (e.g. for drawing graphics) are automatically located and included by the virtual machine

Analyzing Your First Program

 A Python program contains one or more lines of instructions (statements) that will be translated and executed by the interpreter

```
# My first Python program
Print("Hello World!")
```

- The first line is a comment (a statement that provides descriptive information about the program to programmers).
- The second line contains a statement that prints a line of text onscreen "Hello, World!"

Basic Python Syntax: Print

- Using the Python 'print()' function.
 - A function is a collection of programming instructions that carry out a particular task (in this case to print a value onscreen).
 - It's code that somebody else wrote for you!

Syntax for Python Functions

- To use, or call, a function in Python you need to specify:
 - The name of the function that you want to use (in the previous example the name was print)
 - Any values (arguments) needed by the function to carry out its task (in this case, "Hello World!").
 - Arguments are enclosed in parentheses and multiple arguments are separated with commas.
 - A sequence of characters enclosed in quotations marks are called a string

Our First Program

```
##
   Sample Program that demonstrates the print function
#
  Prints 7
print(3 + 4)
 Print Hello World! on two lines
pri nt ("Hello")
print("World!")
  Print multiple values with a single print function call
print("My favorite number are", 3 + 4, "and" 3 + 10)
  Print Hello World! on two lines
pri nt("Goodbye")
print()
print("Hope to see you again")
```

Errors

- There are two Categories of Errors:
 - Compile-time Errors
 - aka Syntax Errors
 - Spelling, capitalization, punctuation
 - Ordering of statements, matching of parenthesis, quotes...
 - No executable program is created by the compiler
 - Correct first error listed, then compile again.
 - Repeat until all errors are fixed
 - Run-time Errors
 - aka Logic Errors
 - The program runs, but produces unintended results
 - The program may 'crash'

9/5/2019 33

Syntax Errors

- Syntax error are caught by the compiler
- What happens if you

Miss-capitalize a word: Print("Hello World!")

Leave out quotes print(Hello World!)

Mismatch quotes print("Hello World!")

Don't match brackets print('Hello'

• Type each example above in **PyCharm**

What error messages are generated?

Logic Errors

What happens if you

• Divide by zero print(1/0)

Misspell output print("Hello, Word!")

Forget to output Remove line 2

Programs will compile and run

• The output may not be as expected

• Type each example above in **PyCharm**

• What error messages are generated?
